GARDENING

Illustrated.
For Town & Country.

A Weekly Journal for Amateurs and Gardeners.

FOUNDED BY W. ROBINSON,

*Author of "The English Flower Garden," "The Wild Garden," "Hardy Flowers," "Alpine Flowers," &c.
Founder of "The Garden" and "Farm and Home."*

"YOU SEE, SWEET MAID, WE MARRY
A GENTLE SCION TO THE WILDEST STOCK
AND MAKE CONCEIVE A BARK OF BARKER KIND
BY BUD OF NOBLER RACE; CHANGE IT RATHER: BUT
THE ART ITSELF IS SATIRE."—*Shakespeare.*

"CALL THE VALES AND BID THEM HITHER COME
THEIR HILLS AND FLOWERS OF A THOUSAND HERS."—*Milton.*

VOL. XV., FEBRUARY 24, 1894.

LONDON:

OFFICE—37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

THE PINK.

There are two prime features in a good Pink; one is its exquisite fragrance, and, unlike many of the Carnations — one might say most of them — which are generally devoid of fragrance or possess it only very faintly, the Pinks are all sweet-scented; it seems to be a condition of their nature. The other is the lacing on the petal margin in a well-developed flower so dense and regular. Given, then, a full bloom that is of full substance, pure in the ground, and regularly laced with some shade of purple and purple-crimson, or lilac through shades of red to crimson, and there is a flower worthy the acceptance of anyone. To have Pink blossoms of large size and finely laced, the plants should be grown in a well-prepared bed in the open, made up of

rich soil, and the plants placed in it in October. It is only plants which are thoroughly established that can be expected to have well-laced flowers. It is sometimes said of the Carnation that it is coddled and debilitated by being kept in cold frames through the winter, but this same cannot be said of the Pink, which is grown wholly in the open and thoroughly exposed to all weathers. The soil of most gardens will grow Pinks. If it is a good yellow loam, or a black one of good heart, so much the better. If this be dug in September, and road or river sand, the former from a gravelled road, the latter from a shallow, fast-running stream, and well-rotted manure be freely added, then there is a good bed for Pinks.

ROAD-SCRAPINGS with horse-droppings make good ingredients for a Pink bed, and the root-fibres run freely in it. It is not too late to plant such a bed, but the best plants for placing in a bed in January or February are those which have been wintered in pots, because they are certain to have rooted well, and they can be placed in the ground without disturbing the ball of roots very much. Plants lifted from the open ground at midwinter or in early spring are apt to lose the soil about the roots, and then a decided check occurs. I have known orders to come to a nurseryman for Pinks so late as April. When they have got into active growth it is practically impossible such plants can bloom well, because they are checked in their progress late in the season. A few good laced Pinks are to be found in Clara, the laced reddish-purple, a flower with stout and finely-rounded petals. Rosy Gem has a paler lacing, very broad, and the blossoms sweetly fragrant. Henry Hooper has a rich dark lacing, a flower of large size, full, and very handsome.

One of the best is Boiard, a favourite flower with all growers, a good grower, laces well, and very full and fine. Modesty is remarkable for its pale pinkish-lilac lacing, sometimes deepening to bright rosy-purple; it is very early and free, and makes a charming border variety. Another excellent border variety is found in Mrs. Walte, small, very pretty, and free. Beauty is another small-flowered variety, but very free to cut from. A very fine Pink is found in Empress of India; it is very distinct, fine in colour, the lacing rich and deep. The Rector, very fine; Minerva, Jessica, Eurydice, Device, George White, Excelsior, very fine, are also good laced varieties, and it is worthy of remark that some of the before-mentioned have been in cultivation thirty and forty years. Some persons might be led to think the laced Pinks are all alike, but there is more difference between them than is usually fancied, and cultivators who become acquainted with their peculiarities by growing them are able to detect marked differences between the varieties. Three

NEW VARIETIES of laced Pinks (raised by Mr. James Thurston, of Cardiff), were last year distributed from Manchester. They are James Thurston, John Dorrington, and George Hodgkinson, all remarkable for the purity of the ground colour, fine quality of petal, and refined lacing. James Thurston is, in my opinion, the finest laced Pink ever raised, a flower of the highest quality, the other two being also remarkably good. Of fine old border Pinks of various colours, mention may be made of Anne Boleyn, very good indeed, and always in great demand; Rabens, pink, with dark centre; Ascot, pink, with crimson centre; Mrs. Sinkins, white, grown very largely for cutting from; Clifton White, an improvement upon Mrs. Sinkins; end Lord Lyon, a flower of very fine shape, pinkish lilac with dark centre. Of newer border varieties, there are Her Majesty white; Charmor, pink, with dark centre; Beauty of Sals, pale pink, fimbriated, very good; Norah, bluish, with rosy-purple centre; Flirt, pale-pink, with rosy-purple lacing; Charles Lockyer, pink, with deep rosy-purple lacing; Beauty, white, with slight rosy purple lacing; and Fimbriata, soft pink, the petal edges deeply fimbriated. Pinks are

PROPAGATED by means of pipings, which are cuttings of the young shoots from the base of the plant, and layering the same as Carnations, which is a practice much followed in the midland districts. The quickest way to strike them is

to put them in pots of light, sandy soil firmly pressed about the cuttings; place them in a gentle bottom-heat with bell-glasses over them. Or they can be put into sandy soil in the border where there is a little shade, in little clumps, with bell-glasses over them, and they will root, though not so quickly as when the pots are plunged in bottom-heat. The earlier in the summer the pipings can be struck, so much the stronger are the plants for placing in the open ground in the autumn. It is customary to raise a Pink bed 6 inches or 8 inches above the ground-level. This is done that the heavy autumn and winter rains may drain away from the roots of the plants, as, though the Pink is perfectly hardy, stagnant moisture at the roots is found to be very injurious to it. R.

GARDEN WORK.

Conservatory.

Shake out and repot *Tuberous Begonias*; pretty well all will be on the move now. They succeed well in a warm greenhouse at this season. If those plants intended for beds are kept cool they will be stronger and better. Loan two-thirds, with one-third leaf-mould and some sand to keep the soil open, will be a suitable compost. If seeds are sown now in the hot-bed they will all bloom during the summer if sown on 11th June in heat. The winter-flowering Heaths that were shortened back after flowering will now have broken and may be repotted. Use the best peat obtainable, made porous with clean sand, pot firmly, and water carefully till the roots get into the new compost. Many hard-wooded plants are ruined through having too much water after repotting. *Azaleas* which have completed flowering may be shortened back to put the plants into shape. These *Azaleas* planted in the borders will require rather hard pruning to keep within reasonable bounds. Put on young *Fuchsias* and other soft-wooded plants which are growing freely and require more root space. Now seeds of *Balsam*, *Chinese Primulas*, and a pinch of *Cineraria* seeds for early blooming. *Primula obconica*, in spite of its bad reputation, is a very useful subject for winter flowering in the cool or warm conservatory. Seedlings raised now will make useful flowering stuff in 2-inch pots by the autumn. As the forced bulbs go out of blossom move to a cool pit to complete and harden growth, when they may be planted out; they are not of much use for pot culture afterwards. Most plants will require more water now; the borders also where *Oleanders* are growing must not be overlooked. Liquid-manure will be useful to specimen *Roses*. *Tansy* and other *Marigolds* planted out in a warm house will now be full of blossoms and buds coming on rapidly; this beautiful *Rose* still holds the leading position among *Yellow Roses*. Liquid-manure will give size to the blossoms. Use *Autumn* or some variety ready on the first appearance of mildew. In ventilating avoid cold draughts. Insects must be dealt with promptly, either by fumigation or soap and water or Tobacco-powder; the last named I find very useful where only a plant or two is infested. The *Springer* may in some cases be used on fine mornings. Lily of the Valley will come on now without very strong heat, and the flower-spikes will last longer. *Azaleas*, both the Indian and Japanese species, are now a special feature, and will require liberal supplies of water. *Sulcata Japonica* may, with advantage, be forced in cases half filled with weak liquid-manure. It is too soon yet to commence shading to any great extent; but *Azaleas* in bloom will last longer if a temporary shade can be placed over them for a few hours on very bright days. Cuttings of young shoots of *Abutilons* will strike now in heat. Repot *Orange-trees* if they require a shift or the soil renewed. Keep *Kalassans* in a light position near the glass to ripen growth.

Unheated Greenhouse.

This house may now be gay with hardy bulbs and other early-flowering hardy plants. *Dialytis speciosa*, *Lily of the Valley*, *Solomon's Seal*, *Spiraea* of sorts, early-flowering *Rhododendrons*, *Kalmias*, *Betula*, *Asplenium*, and the hybrid forms which have been obtained from it, will flower early in a cold house; they are quite hardy, and, being so early to bloom, will be valuable. *Bambusa* in variety, if the house is large enough, will form a pleasant feature under the shelter of a glass roof; they will be more effective than most of them are in the open air, unless the position is warm and sheltered. *Aurucias* and other members of the *Primrose* family are indispensable for the cold house; they are perhaps better adapted for a small house than a large one, although always and everywhere they are very interesting. A little top dressing will help this family now.

Stove.

Cuttings of ornamental-leaved *Begonias* will strike now quickly. Plants may be raised from leaves only; but good cuttings are better, as plants are more speedily formed. The early-started *Gloxinias* will now be in blossom. I find seedlings more manageable in this respect than plants raised from cuttings; they have more vigour. Seeds may be sown now, and, if well attended to and kept growing, the strongest will flower in autumn. *Streptocarpus* hybrids and the *Sultan Balsam* (*Impatiens Sultan*) may be sown now in sandy peat. Prune specimen plants of *Vicia's* *rosas* and *oculata*, and repot as soon as the plants get fairly into growth. Cuttings of the young shoots will root quickly and form useful little flowering plants during the summer; these plants will not flower well if under-potted. Plenty of moisture in the atmosphere is also essential. Get in cuttings of *Polkastris* as soon as the young shoots are from 2 inches to 3 inches long. *Torenia* *asiatica* and *Fountain* may either be raised from seeds or cuttings; cuttings are best. If young, soil shoots can be had. Get in a good stock of all the usual winter-flowering stuff, such as *Pentaea carnea* and *rosea*, *Seriographis*,

Thyracanthus, *Plumbago rosea*, *Justicia*, *Eranthemum*, &c. Sow seeds of *Violas humilis*, a very pretty berry-bearing plant, useful for table and room decoration in winter. In very bright weather certain plants will require shade, and more water must be given to the plants and used about the floors to saturate the atmosphere. Night temperatures need not exceed 65 degs. Avoid cold draughts in ventilation; the time for keen, cold winds and brighter skies is near. Start *Abutilons* and encourage *Genesee* to continue resting for the present; for that reason I prefer to keep these bulbs dry and cool for another month.

Bedding Plants.

Where many of these are required an sowing time lies before us. Cuttings of all soft-wooded plants will strike now in heat, either in the hot-bed or from fire-heat. I have struck many thousands of bedding plants in the hot-bed. When I did a good deal of carpet bedding all the tender things were struck in slight hot-beds during the months of March and April. The usual plan was to make up a hot-bed the heat of which would last about a month, cover it with light sandy soil, and, as soon as the heat had worked through and staidied a bit, dibble it full of *Alternantheras*, *Coleus*, &c., leaving each cutting space enough to grow into a decent sized plant. In the course of two or three weeks the plants will have rooted, and may then be topped, and a second series of cuttings dibbled into another hot-bed. In this way many thousands of plants may be worked up from a small stock.

Cold Frames.

Calceolarias will do very well here now, and the frames will also be in useful for moving plants to from the conservatory, and, if well covered at nights, surplus plants from the greenhouse may be moved out to the frames to give more space to this rapidly-growing *Geraniums* and other things.

Window Gardening.

Window-boxes are now gay with bells. *Crocuses*, *Daffodils*, *Blue Squills*, and *Snowdrops* are charming now outside some windows. Inside also there is no lack of bloom - *Cinerarias*, *Primulas*, *Cyclamen*, *Azaleas*, *Genietas*. Pots of *Trumpet Daffodils* and *Jonquills* are pleasant to look upon. *Hyalinths* and *Dutch bulbs* generally are flowering well this season. More water will be required now, though, if a little green Moss is placed on the top of the pots, less water will be needed, and the appearance of the bulbs will be improved. Keep down green-flies with the sponge and soapy water.

Outdoor Garden.

The ground is in good order now for tree and shrub planting, and deciduous things especially should be got in. The planting of evergreens may be done any time up to the end of April or even later. It is a good many from a good nursery where the plants are frequently transplanted, and it is this frequent transplanting in the nursery which makes their removal safe at almost any season a matter of certainty. All ground intended to be planted this season with trees and shrubs should have been trenched and got into good condition. The plots do so much better where the ground has been well prepared. Look or alpine plants may be divided and replanted now, new soil of suitable character being added where necessary. In fact, it is always advisable to work in fresh soil in replacing most things of this kind. Fix every plant firmly in the ground; when loosely planted they dry up and perish. Many *Carrots* and other plants die annually through not being pressed down after root. *Carrots* require to be very firmly fixed in the soil if they are to do well. Herbaceous plants of all kinds may be planted now. Choose things which have been plunged in frames may be set out. Of course, before doing this, a system of full exposure should have been followed for some time previously. Prune *Aliburns* and get early *Blossoms*. Mince over the roots of newly planted *Roses* and shrubs; it increases the chances of healthy and vigorous growth. Let everything be staked in windy places.

Fruit Garden.

Peaches in the early house will now be set, and as soon as one can see which fruits are taking the lead in the swelling the smaller should be removed. It is so important nowadays to have large Peaches that everything possible should be done to give size and colour. For the same reason, disbudding should be promptly and early done, and with a fearless hand. The dangers of leaving too many fruits and the young shoots too crowded are so great that I would rather err in the opposite direction if an error is committed at all. See that all inside Peach borders are perfectly moist. Outside borders are sure to be moist enough now. Vigorous young Vines will break strongly, and the shoots should not be permitted to run into each other before stopping and tying down. Two leaves beyond the bunch should be left if possible, and the tying down should be done by degrees. As buds on fruit-trees outside are on the move, Get Peaches pruned and trained without delay. In pruning, take out any old branch wherever there are well-placed young shoots to fill. Peach-trees which have been troubled with black-fly should be washed with *Gehurst* compound or some other suitable mixture; soft-soap or Tobacco-liquid will do as well. A soft brush or bit of sponge drawn the same way as the buds point will be convenient and safe. On the whole, judging from the appearance of the trees, there seems to be a fair prospect of bloom. Pears on the *Quince* when the land is fairly bearing are looking promising, but the *Quince*-stock is not adapted for light, sandy, or calcareous soils. Cuttings of hush fruit may be planted, and *Raspberries* shortened and mulched. *Raspberries* may be very well grown without stakes if cut down to 3 feet.

Vegetable Garden.

Where the *Carrot-fly* has been troublesome in previous years give the ground a good dressing of salt and lime; paraffin-oil has been a very useful remedy mixed with water and the ground moistened with it a week or two before sowing the seeds. I have used a quart of oil to 16 gallons of water. This remedy is cheap enough, and the millions of *Globe Artichokes* are required, the ground should be well manured and got into good condition ready

for planting the end of the month or beginning of April. Plant in rows 4 feet apart each way. Good strong sets are better than small offsets as regards immediate results. Sow *Asparagus* seeds to raise early plants, and plant out the *Seakale* cuttings which were cut from the crowns taken up for forcing; they may be planted with the dibble in rows 15 inches apart and 1 foot apart in the rows. Prepare ground for planting with *Asparagus*. As soon as the young ground starts away, *Lettuce* plants or other vegetables raised in heat, to be hardened off and pricked out in the border or outside rows along the foot of a south wall, will grow rapidly. Keep the *Blue-room* houses steadily at a temperature of 55 degs.; if Cucumbers are wanted quick 70 degs. will be best, but I am not in favour of high temperatures when fire-heat is to do the work. On sunny days I would let the thermometer run up to 95 degs. or 100 degs. with plenty of moisture in the atmosphere. Planting out *Cauliflowers* in trenches. We have no lights for them, but the plants are sheltered with borders. There is a good deal of protection in the leather spray of the branches of *Hazel* usually cut for *Pest-locks*. Sow main crop of *Celery* on a gentle hot-bed. K. HOBDAV.

Work in the Town Garden.

Lose no time in sowing seeds of *Petunias*, *Verbenas*, *Lobelias*, *Mimulus*, and other greenhouse and half-hardy bedding plants. The *Nicotianae* or *Tobacco*-plants grow very fast and strong in rich soil, even in the smokiest places, and even the ordinary kinds (*N. glauca* var.) are valuable as affording plenty of fine foliage, if not much else, while the deliciously fragrant *N. glauca* is also an excellent town plant, and one that everyone should grow, both indoors and out. Sow now and treat the same as *Petunias*, and the plants will be in full bloom in July and August. A few *Balsams* may also be sown either large plants or early flowers are wanted. These are capital town plants and very easily managed, the chief points in their culture being rich, mellow soil and plenty of light and moisture both at the root and overhead. *Tuberous Begonias* and *Gloxinias* also sown at once in a moderate heat will still bloom before the autumn if kept moving on briskly. These are often recommended to be sown in January or February, and in country places this is right enough; but even if one gets them up so early in the atmosphere of a large town, before they are fully started, it is not likely to impart substance to the growth, the plants are weakly from the first, and even if they do pull round afterwards are little, if any, more forward than those not sown until the end of February or early part of March. Seed of the new *Streptocarpus* hybrids sown now will also produce flowering plants by the month of August. Seed of this plant is very minute - about the smallest I know of, in fact - and therefore requires to be sown on a very fine and even surface, and the greatest care must be bestowed on the young plants during the early stages of their growth. A few *Tomatoes* may also be sown, if so much *Tomatoes* ought to be sown at once. These, again, I have often sown in January and February, in different suburbs of London, but nearly always had the seedlings go off in cold, foggy weather afterwards; whereas, if left until about the present time, they would grow right away from the first, and beat the others hollow. *Pisces* roots of *Dahlias*, from which cuttings are required, in heat, with a little light soil round them, keeping them in a moderate temperature, will be in full bloom by the month of August. *Epilobium*, *double Petunias*, *Heliotropes*, *Marguerites*, and others in a gentle hot-bed, and pot them off singly when rooted; *Begonia tuberosa* for bedding, and very small roots should be dibbed out in boxes of light sandy soil to start, but choice kinds had better be potted singly. B. O. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from March 4th to March 11th.

Removed *Strawberries* just beginning to colour from the hot-house to a cooler house, where more air is given. This will improve the flavour and tend to solidify the texture of the fruit, and they will travel better. Introduced more *Strawberries* into heat to come on in succession. With me there must be no break in the supply, and to accomplish this regular fortnightly introductions will be necessary. Looked over planting and other protecting covers that will shortly be needed. The plants which are present there are no blossom open, though some of the *Epilobium* on the south wall are just showing colour. Finished training *Peaches* and *Nectarines*. Removed coverings from *Figs* on walls; they will be safe now from frost; though, in the unexpected event of a very sharp night coming, mats would be hung in front of the trees. At present the wood is clean and bright; and the pruning will not be done till the end of the month. Beyond a few early *Roses* on the south border, no pruning has yet been done, and, as the growth is later than usual, shall not prune the collection until the end of the month. - Tea a few later, but I should state that some of the longest shoots were shortened a little in the autumn to ease the wind pressure. Disbudded *Peaches* under glass. Watered inside borders. Stopped and tied down Vines. Finished thinning *Grapes* in early house; shall go over them again later on and remove small berries, and possibly take a berry or two out where there are any signs of crowding. Planted *Tomatoes* under glass; the plants are strong and showing blossoms. A temperature of 55 degs. to 60 degs. at night will be kept up; and under such conditions the plants will grow fast and set well. Ventilate plants as they are given when the weather is suitable, but I object to cold currents, as being likely to bring on disease. The plants are never syringed but water will be given when required, and it is to this dry, buoyant atmosphere I attribute the absence of disease. Top-dressed *Cucumbers* with turfy loam enriched with a little old manure. Shifted *Melons* into larger pots to grow on until house is ready. Sowed *Chinese Primulas* for early blooming; a later sowing will be made for spring blooming. Gave *Fuchsias* the third watering. - Tea a few more plants in rather smaller pots, and to obtain good heads of bloom they must have extra support. Planted more *French Beans* in pots, also prepared a pit for sowing it with fermenting material for bottom-heat. They will be planted with *French Beans* as soon as ready.

* In cold or northern districts the operation referred to under "Garden Work" may be done from the beginning to a fortnight later than is here indicated with equally good results.

Sowed tender annuals of various kinds, including Victoria glorioza, Phlox Drummondii, East Lothian Stocks, Victoria Asters for early planting, Zinnias, &c. It is not difficult to make beds in gardens very bright by seedlings alone. Stirred the surface among Pansies, Carnations, and other plants. It would be an advantage, if time permitted, to stir the surface soil every week or ten days, doing the work, of course, when the soil is dry. Such treatment effectually keeps down weeds and increases the vigour of the plants in the beds. Plant more Peas and Beans, Potatoes, &c. Sowed more Horn Carrots, and Radishes, and a few rows of Egyptian Turnip-rooted Beet. Some few of the plants may perhaps bolt, but the other roots will come in useful.

OUTDOOR PLANTS.

3112.—Hardy perennials from seed.—A great quantity of hardy plants may be simply and easily raised from seed, but not many of them will bloom to any extent during the same season. To obtain blooms for this year it would be wiser to rely upon the better hardy and half-hardy annuals, and meanwhile pay attention to securing a good stock of the best perennials ready for planting in their permanent positions next autumn as soon as the annuals have done blooming. The following are some of the fine families of which plants may be raised from seed with no more trouble and cost than is

bloom for cutting you must make up a permanent bed, planting the crowns at a distance of about 3 inches apart, and give the surface a dressing of well-decayed manure. Give ample supplies of water, and a mulch of manure each year will prove beneficial. Such a bed should give good flowers for years, and will not need to be disturbed until the crowns get so crowded that vigorous growth is impossible. If you rear them merely for the garden the chief requisites are moisture and shade.—C. T.

3188.—Culture of Pinks.—These like a good medium loam, and are easily grown; but this is not the season of the year to plant them. Probably they could be obtained in pots now from some florist who makes a speciality of them, and if planted in soil deeply dug and enriched with decayed farmyard-manure, they would flower this year, but the flowers would be of poor quality, and they would be badly laced, or perhaps the lacing would be gone altogether. To obtain good results the bed should be prepared early in the autumn, and the plants should be set out where they are to flower in September or October. This planting out should be done as soon as good, strong plants can be obtained. It is a great point to get

white and other Lilies. These might be arranged in groups, and the soil for each group could be specially fitted for them. Before anyone should decide how to lay out a small garden a decision should be come to as to what the soil will grow best, and the tastes of the proprietor. There is no pleasanter way of laying out a small garden of the size indicated than to run a winding walk through it, with a few choice shrubs at the back, or a fruit tree or two, and the flowers grouped around them. The shrubs and trees need not form a continuous line, but one placed here and there, leaving openings between for groups of such plants as Hollyhocks, Delphiniums, standard Roses, &c.; nearer the walk would come the dwarfier things—Carnations, Tea Roses, Pinks, &c.; in the centre or in some of the recesses between the shrubs and trees would be spaces for Cactus Dahlias, White and other Lilies, Phloxes, German Iris, &c.; in the shady spots would be places for Ferns, Primroses, and, of course, positions would be found for Aconites, Snowdrops, Daffodils, and other bulbs. There is scope for a good deal of thought in the laying out of a small piece of ground if the best is, to be made of it.—E. H.

— If I knew what kind of fence surrounds your garden I could help you much better than I can in the absence of such information. I should say a walk 3 feet wide down the centre would be all the walks you require. In that case a bush Apple-tree may be planted on each side at the farthest end—say 8 feet inside your boundary—and 6 feet from the edge of the walk on each side. The best sorts of Apples for your purpose are Echlinville Seedling (early), and Lane's Prince Albert (late). A few Gooseberry and Currant-bushes may also be planted near to the Apple-trees. Next to these a line or two of Raspberries, and then a bed of Strawberries about 6 feet wide on each side. The remaining space you may fill up with a row of Scarlet Runners, Vegetable Marrows, and a few early Potatoes, and such other vegetables as you require. If you devote any part of the ground to flowers, they will, of course, be near the house.—J. C. C.

3151.—Garden-path.—I should say the best thing to do would be to get the ground out 12 inches or 18 inches, and put some rough ashes (hard burnt) in the bottom and the finer ashes on the top. This would make a good path.—T. J.

3130.—Tiles for garden borders.—Why not substitute as an edging some pretty plant, such as the Mossy Saxifrage, Thrift, London Pride, Primroses, Polyanthus, &c., a few of which have been mentioned in recent numbers? They are much more interesting than hard tiles, never beautiful at the best. The Thrift makes a charming edging, and is smothered with bloom at the time of flowering. Put in good tufts at once, and if they do not meet the first season, they will next year, making a soft, felt-like edging. Auriculas are very pleasing in the spring, and if you do not care for such things as these, make an edging of Grass or some strong-growing Ivy, as the Irish. I should much prefer a pleasing tufted plant or creeper than the earthenware tiles.—C. T.

3185.—Forget-me-nots.—The variety you have seen is probably *Myosotis dissitiflora*. The cultivation is very simple. Let one plant scatter its seed, and in the following spring you will be able to take up and plant where you require them hundreds of strong young plants. The trouble with *Myosotis* is not to multiply, but how to keep it within bounds.—A. G. BURTON.

— The best blue Forget-me-not is *dissitiflora*, though this sometimes comes with a tinge of red in the flower. It is very neat and compact in habit, and flowers freely. There is also a white variety. *Robusta grandiflora* is also a good kind to grow. *Palustris*, the Marsh Forget-me-not, is a good variety for a shady border. I think anyone possessing these varieties will not require others. All the plants may be raised from seeds sown in a shady border in June. *Dissitiflora* is sometimes increased by division, as the seeds are dearer than the other varieties.—E. H.

— *Dissitiflora* is the best variety to grow where compact plants with plenty of deep blue flowers are required. A packet of seed sown on a warm border at the end of May will give a quantity of plants that should flower really well the following year. When they are large enough to handle they should be pricked out into another bed to gain strength, as if they are allowed to remain in the seed-bed they are sure to be drawn up weakly, and, of course, unfit for good flowering. As early in October

A Primrose (*Primula vulgaris*) in the wild garden.

incurred in raising stocks of annual or tender things: Achilles, Alyssum, Anemone, Aquilegia, Armeria, Aeter, Anubria, Campanula, Chelone, Coreopsis, Delphinium, Dianthus, Dracocephalum, Echinops, Erigeron, Eryngium, Gaillardia, Goum, Gypsophila, Helenium, Iris, Lathyrus, Linaria, Lupinus, Lychnis, (E)others, Papaver, Pentstemon, Phlox, Primroses (see illustration), Rudbeckia, Scabiosa, and Veronica. I had great success some years ago by sowing the seed of many of these direct into an open border, but it had fine, friable soil. I much prefer sowing outside in preference to pots and frames, cuttings being favourable, as, if care is exercised to sow thinly, the young plants grow away unchecked, encounter no vicissitudes, such as arise from neglect to attend to them—often accidental, it is true, when in pots—and they make much stronger growth in a given time. May and June are two good months for sowing seeds of perennials in the open air.—A. H.

3119.—Lily of the Valley.—Strong crowns planted now will produce flowers this season. A rich, partially shaded position is best for them. After planting mulch with old leaf-mould or very old manure.—E. H.

Your plants would not do great things this year. The best time to plant in the autumn, as early as possible after the foliage has died down, and this flower enjoys a moist, moderately shady spot. But if you require plenty of

them out in time to become established before bad weather sets in. The sorts I have found to be the best are *Attraction*, *Bertram*, *Boiardi*, *Clara*, *Now Criterion*, *Emerald*, *Godfray*, *Henry Hooper*, *Jessica*, *John Ball*, *Lady Craveu*, *Mrs. Waito*, *Empress of India*, *Reliance*, *Shirley Hibberd*, *William Paul*, *Eurydice*, *Modesty*, *Pandora*, and *Lottie*.—J. D. E.

3197.—A small garden.—There is plenty of room for a couple of Apple-trees in your garden, and if they are standards they might stand back a little in the corners if the garden is square. The walls or fence might also be covered with fruit-trees. Apples, Pears, Cherries, and Plums will grow very well on a close wood fence. As regards the garden generally, the question should be put—what do you want to grow and what are your own tastes? As a rule, in small gardens, not only the outline but the entrance and the paths are arranged beforehand by the builder's men. Where the entrance is in the centre the Apple-trees might stand one on each side, and, if tall, creepers may be trained up the stems. There would not be room for many vegetables in such a garden, though Herbs, Beetroot, Carrots, and Scarlet Runners may be grown, as they possess some decorative value. Among flowers there should be Roses, Carnations, Hollyhocks, Violas, old

as possible the plants should be put out into their permanent quarters, to enable them to make fresh roots before the autumn rains and cold weather come on. Although seedling plants come generally true from seed there are certain to be some few "rogues;" these should be marked and weeded out after flowering in past. The old plants, if dug carefully up after flowering, and laid in thickly on a border, make the best stock for another year with but little attention being required, if the strain is worth perpetuating. The first week in August pull the plants in pieces, dibbling every bit with a root attached to it in rows 8 inches apart, on any open piece of ground, shading them with boughs for a few days, if necessary, to prevent the leaves flagging much. By the time for planting out these slips will have grown into compact, bushy plants of a known strain of colour and form. There is more certainty about plants raised in this way than from seed, hence its advantage.—S. P.

3198.—Sweet Peas.—The seed saved last year from good varieties will produce good varieties again this year, but if there were a mixture of several varieties in the same row, pollen of one variety would be carried to another, and hence different varieties would be the result. Some of them might be better than the parents, others not quite so good. If one variety could be kept by itself, so that the pollen of a different sort could not reach it, there would be but little variation from the original. I have frequently saved seed from a row of mixed Sweet Peas, and had good variety and excellent sorts from it. As to the varieties being "reduced to a few indistinct ones," this is not likely to happen, although the stock would not be improved by indiscriminate saving of the seed.—J. D. E.

—There is no reason why the flowers should not be satisfactory next year. I have often saved my own seed, and got excellent results. Of course, you must not keep on growing them in the same place unless the soil is prepared.—C. T.

3199.—Daffodils.—It seems any plant to cut the flowers, Daffodils among others.—E. H.

—These plants would be likely to form better roots if the flowers are cut off as soon as they open. As long as they remain and are allowed to form seed-pods they take something out of the bulbs, and the longer the leaves remain green the better. When hot weather sets in the leaves soon take upon themselves the yellow hue of decay; to prevent this, water freely to encourage first the full development, and afterwards the ripening of the bulbs.—J. D. E.

—Undoubtedly the bulbs will do better if the flowers are cut when they are fully expanded; but in a suitable soil there will not be so much difference in their future behaviour as one might imagine. At the same time, if you find the bulbs getting weaker, cut off the flowers by all means. Seeing how the behaviour of Daffodils varies in different soils, I find they do better where the ground is fairly moist below.—J. C. C.

—Your Daffodils, if in proper health, may, of course, be left to flower, but if the bulbs are very weak remove the flower, so as to throw strength into the root. In the culture of the Daffodil, a good well-drained soil is of first importance, and the bulbs detest stagnant ground, this being the reason why growers always raise the beds a little from the level, so as to prevent wet remaining around the bulbs. Perhaps the Daffodils have got into poor condition through want of lifting. It is well to lift the bulbs when they appear to be exhausted and give them fresh soil. Take them up when the foliage has died down, and replant early in the autumn. The Poet's Narcissus should be planted first.—C. T.

3202.—Culture of Christmas Roses.—Helleborus niger is not a difficult plant to grow, and there are many beautiful varieties yet. The following are the finest, and may be selected without fear of getting two or three alike. Maximus, also called latifolius, is the finest, and a very popular form. The flowers are large, and of the purest white, except in exposed spots, when they are tinged with rose. Its foliage is very handsome, deep-green and leathery. The bulb variety, caucasicus, very free-blooming, the flowers white, touched with rose; angustifolius, white, with a suspicion of rose on the outer surface of the segments;

Mme. Fourcade, the flowers very large, of the purest white, and of great beauty. If you care for a number of varieties extend the list to W. Brockbank, the flowers brood and pure white; Riverton hybrid, and vernalis. The foliage of the Helleborus is very striking, and I hope you are not foolish to rub it off with the idea of benefiting the plants. If you want to kill them that is a good way to do so. As regards soil, much will depend upon the character of the garden. If you already have a deep rich soil you need not further prepare it, but if poor and sandy, add some good loam and manure. A stagnant situation is hurtful, but a cool, moist, partially shady spot agrees well with them, and in half-wild spots, by the margin of shrubberies, on the rocky, and in other spots likely to agree well with them, the plants will grow and flower well. Once planted they need not be disturbed for some years, as there are few plants that resent interference more at the roots than the Helleborus. There are two ways of propagating them, by division of the roots and by seed, but you will commence with good plants, which is by far the quickest and most satisfactory way of getting home-grown examples. In light soils give a mulch of well-decayed manure in the summer season if the weather is very dry, so this will help the plants to make a satisfactory growth. If you have a greenhouse put up a few plants, as they will bloom when flowers are welcome in the house, and under cover the flowers expand in fullest beauty, not being splashed with soil from heavy rains. A very good plan is to have a reserve bed, and put a handlight over the most promising clumps when the flower-buds appear. The flowers will then open fresh and unspoiled by the weather. In large gardens the clumps are lifted and placed in baskets. A gentle heat brings them on apace, and they produce a quantity of flowers for the table. Those potted up for the greenhouse must not be used the following year. Plant them back in the garden when frosts are over to prevent the leaves being destroyed, as they will be tender. If this is not done the plants will be considerably weakened.—C. T.

2212.—Daffodils failing to bloom.—Perhaps you have overdone them with manure. A very rich soil is not necessary to grow Daffodils well, but in an ordinary garden ground, well prepared and not wet, a fine growth results. If you have had the bulbs several years, as appears from your query, possibly they require lifting. It is wise to lift Narcissus once in every two years, but situations must be taken into account. The paucity of bloom may result from a poor soil, and therefore lift the bulbs when the foliage has died down. Choose a new site, or prepare the old one by digging in well-decayed manure. Plant again in early autumn.—C. T.

3196.—Manure for a garden.—You may use the pigeons' manure for the plants you mention, and in the way you propose, if you dig it into the ground or mix it up in the soil in which you are planting. You may also use the manure alone as a top-dressing if you water it each other day. It is, however, a powerful stimulant, and must be used with care, or you will get plenty of foliage and but few flowers. One quart of the manure will make 4 gallons of strong liquid, which may be given to plants just coming into bloom.—J. C. C.

3211.—A wind-swept garden.—It is usual to recommend the planting of some evergreen trees, such as Spruce Fir, for such a case as yours, but I do not think evergreens of any kind are suitable where the wind sweeps down with so much force as in this case. If it was my case I would plant two rows of English Elm-trees in the border, and as soon as they had reached the required height I would take off their tops. If the trees are planted 6 feet apart each way, and the outer row set in the openings of the other, they will quickly fill up the space and prove a perfect barrier to the wind. For the first few years the trees would not want any pruning; but after that the side branches will require cutting in, so as to form a hedge on an enlarged scale. There is no deciduous tree, not even the Lime, that submits better to this form of growth, and, at the same time, forms a good wind-resisting thicket. Within a short distance of where I write there is a farm premises provided in this way, and it answers admirably.—J. C. C.

ROSES.

3105.—Pruning Roses.—I should have been able to answer your query much more direct if you had given particulars of the locality and also the class of Roses you wish to prune. Therefore, I will endeavour to give a general reply, and one which I hope may be of service to many of my readers. The middle of March is quite soon enough for pruning the very earliest kinds of Roses, such as the Banksians, Austrian Briers, Chians, and Hybrid Bourbons, while the end of the month is an excellent time for the Hybrid Perpetuals, Teas, and Noisettes. I would not prune before the first week in April. The times here given are for plants growing in the south and south-western counties, and are also applicable to Ireland. In the midlands it will be well to defer the operation another week or ten days. Much also depends upon the seasons; but, during an average season, I think the above dates the best. Now a word as to the operation itself. If your plants are of extra vigorous growth, such as Marechal Niel, R6ve d'Or, or Gloire de Dijon among the Teas and Noisettes, or Gabrielle Luizet, Ulrich Brunner, &c., in the Hybrid Perpetuals, they will need very little pruning. Should the wood be crowded, you may commence by removing the weakest, and then shorten back the other wood made last summer to about three-fourths of their original length. Do not cut away more than a third under any consideration. The Banksians, and, in fact, all these known as climbing Roses, need the same treatment. Average growers, like Marie Van Houtte and Anna Olivier among the Teas, or Alfred Colomb and Mrs. John Laing in the Hybrid Perpetuals, need cutting back about half their length. I am assuming you wish for a full crop of bloom, and not for a few of extra merit. If you wish for the latter, you must prune harder. Next we come to the weaker growers, like Souvenir d'Elise Vardon, Etienne, Levet, &c. These should be cut back to the most promising eye lying between 3 inches and 9 inches of the shoulder each growth breaks from. An excellent general rule is to cut the plants harder according to the weakest of their habit. All of the very strong growers flower best from the wood made the previous season, and, if such growth be removed too closely, you only get a further supply of the same wood, and which will not flower until the following season.—P. U.

3108.—Rose W. A. Richardson. If your plant is too high it will not be of very much service to cut it down, because it would only produce more growth, and soon reach the same dimensions again. Unless you can tie or fasten the shoots down in some way, and thus secure the blooms from the long growths that are now in your way, I would advise the removal of the plant entirely, and your placing another grower of less rampant habit in its stead. Madame Falcot, Safrano, or Madame Charles would all give you somewhat after the same colour, and would not grow so strongly. If his sort grows too strongly, you can do no good by cutting it down, because, as I have already remarked, the wood would only replace itself.—P. U.

3162.—Fire-heat for Roses.—Unless you want the Roses in flower early, you may dispense with fire-heat at night all the time the temperature of the house can be maintained at 50 degs. With regard to syringing Roses at this time of year, I may tell you that my first house of Marechal Niel Roses will be in flower before these lines are in the readers' hands, and I have not syringed them once; yet I have had no insects upon them, and, so far, no mildew. Yet the growth is perfectly healthy, and the flower-buds developing to a good size.—J. C. C.

—The Rose is quite a hardy shrub, and does not suffer from frost; and the temperature might fall to 25 degs. without any injurious effect. But, the roots being much exposed when the Roses are growing in flower-pots, they should not be exposed to a very low temperature. They will start to grow in a temperature of 45 degs., and when some growth has been made it will not do to allow the frost in after that, but the temperature might fall as low as 35 degs. without injuring the young growths. It is not necessary, in fact, at night be injurious—to syringe them at this time of the year if no

artificial heat is applied. When they are forced in a temperature of, say, 55 degs. at night they should be syringed daily; it helps to keep off aphid, which is a troublesome pest when Roses are forced.—J. D. E.

3143.—**Propagating Roses by cuttings.**—The question of fertilizing the prunings of Roses in the spring that would be otherwise wasted has exercised the minds of many cultivators besides "Dulwich," who sends this inquiry. And I regret I cannot give him any great hopes of success if the attempt is made of making the cuttings grow into plants. I do not, however, mean that the attempt will be altogether a failure if the operations are carried out with care, because a certain percentage may be made to grow; and the more care given them, the greater the success will be. As a rule, all spineless Roses grow better from cuttings than the others; even those are not so likely to form roots if given bottom-heat at once as when given cool treatment at this time of year. If you wish to try the effect of bottom-heat you had better put several cuttings into a 5-inch pot and then place them in a cold frame, which should be kept shaded in bright weather and quite closed generally. In a few weeks such cuttings as are likely to grow will have formed a callus. If the pots are then placed in bottom-heat they will form roots and in time develop into plants. The bottom-heat should not exceed 70 degs. and the top temperature 16 degs. less. The cool treatment—and which I have found the best—is much more simple. Secure strong cuttings 6 inches to 8 inches long and bury them three parts their length in sandy soil in a north border, and put a frame or hand-light over them, or the cold wind will quickly dry all the life out of them, and so will the sun if you expose them to its influence. The young plants should be left undisturbed until next spring, except the Teas; these would be better if potted in the autumn, and protected during the winter.—J. C. C.

3214.—**Climbing Roses in a conservatory in the Isle of Wight.**—You seem to have treated your plants correctly, but it would have been better if the long growths had been fastened down in a somewhat horizontal manner, then they would have broken into growth more uniformly. As your *Marechal Niel* has been in the border three years, and has made a considerable amount of growth, and from your present description of its weakly breaking I am inclined to think that it is suffering from canker. You can easily discover if such be the case by removing a little of the soil, and noting if there is any abnormal excrecence at the collar of the plant, especially where it was worked upon the stock. If such be the case, take it up and replace with a fresh plant. You cannot successfully cure this disease, and unfortunately this grand Rose is much subject to it. You need have no fear about putting a fresh plant in its place, should my surmise be correct, as canker is not contagious, and very likely the next plant may go on well. It is not too late to bend down the shoots of the other varieties, provided due care be taken not to bruise or break off any of the eyes that may be boring. Up to the present we have not had good weather for Roses under glass, and I trust yours will improve with more sun.—P. U.

3205.—**Marechal Niel Rose.**—No, it is not the draught that prevents the plant growing. I once had a plant in a similar position that remained in the same condition for six years. All that time it did not exceed 4 feet in height, although I done all I could to make it grow. The same thing frequently happens with this Rose, and if the plants do not grow vigorously the second year after planting I over know one to do so after. If you have a good border you cannot do better than put another plant in by the side of it.—J. C. C.

3187.—**Climbing Roses.**—"Hamilton" will find the following list of varieties suitable for his purpose. Climbers: *Gloire de Dijon* (buff and cream), *Reine Marie Henriette* and *Cheshant Hybrid* (red), *Almée Vibert* (small white), *Climbing Perle des Jardins* and *Henriette de Beauveau* (clear yellows), *William Allen Richardson* (orange and apricot), and *Révo d'Or* (pale apricot-yellow). Half-a-dozen varieties suitable for standards: *Mrs. John Laing* (pink), *Boulin de Neige* (white), *Mme. Lambert* (salmon and red), *General Jacque-*

minot (dark-red), *Abel Carrière* or *Fisher Holmes* (velvety-maroon), and *Marie Van Houtte* (yellow). For six dwarf Teas, suitable for outside culture, I can strongly recommend *Anna Ollivier* (buff and peach), *Souvenir de S. A. Prince* (white), *Catherine Mermet* (pink), *Innocente Pirola* (creamy-white), *Mme. Hoste* (yellow), and *Dr. Grill* (coppery yellow). There are so many Roses suitable for your purpose that it is difficult to choose the six best.—P. U.

—Before planting these paint your wire-netting, or it will certainly cut your Roses back. The following will then do well: *Gloire de Dijon*, *Reine Marie Henriette*, *General Jacquemot*, *W. A. Richardson*, *Fortune's Yellow*, and *Almée Vibert*.—A. G. BRYAN.

FERNS.

CHOICE FILMY FERNS.

THE various forms of this genus are popularly known as Filmy Ferns on account of the membranaceous texture of their fronds. This, com-

Frond of a Filmy Fern (*Trichomanes Sellowianum*).

bined with their colour, which is usually an intense deep sea-green, renders them special favorites. In a state of nature the majority of the species are found in shady mountain ravines, and in some instances in dark and gloomy caves, but in all cases where the atmosphere is well saturated with moisture. The atmosphere of an ordinary Fern-house is thus too arid to allow them to develop their beauties. As the majority of the kinds will thrive in a temperature that does not fall below 50 degs., many of them may be used for the embellishment of the dwelling-house in an artistically-arranged Wardian case. The kinds here enumerated, however, mostly require a slightly warmer atmosphere, and I should prefer the thermometer not to fall below 60 degs. during the winter, whilst the summer temperature should not exceed 85 degs. for any kinds. The creeping-rooted forms thrive best upon peatsoot or pieces of Tree-Fern stems, and those with an upright caudex should be potted in peat, loam, and sharp sand, to which

may be added with advantage some nodules and flakes of sandstone. The froods of these plants require to be always moist. I, however, object to the use of the syringe for this purpose, as unless the water is very clean, some impurities are sure to be deposited upon them to their disfigurement. Those kinds which have their stems and rachises clothed with hairs appear to suffer very much from syringing. The sun should never be suffered to reach them, and yet few require heavy shade. If grown in Wardian cases in the house green glass must not be used, and wherever the Ferns are cultivated the Mosses which spring up must not be allowed to increase and choke them.

T. SELLOWIANUM, of which an illustration is here given from a specimen grown in the famous collection of the Messrs. Backhouse at York, is one of the most handsome of the *T. crispum* group, from which, however, it differs in various ways, the chief distinctions being its tufted habit and larger size. A glance at our figure will give a good idea of the extreme beauty of this plant, which is a native of Brazil. *T. crispum* somewhat resembles the preceding, but yet is quite distinct. The froods—from 6 inches to 1 foot long, and from 1 inch to 2 inches broad—are produced from a short decumbent or creeping rhizome. They are sub-pinnate, saving a narrow membranaceous wing, which connects them together. The stem and rachis are clothed with short reddish-brown hairs. Native of the West Indies and Tropical America. *T. KAOLIFU* is a magnificent species, and one that would appear to be plentiful in Trinidad, as I have received numerous consignments of it from that island, where it seems to luxuriate in strong loam. The stem and rachis are clothed with long taney hairs, the froods being from 9 inches to 18 inches high, and about 2½ inches wide; the segments are lanceolate. *T. CRINITUM*: A pretty dwarf-growing plant of tufted habit, with slender hairy stems and bipinnatifid froods, which are broadly oblong in outline; the colour is pale-green, and the fronds appear of a glaucous hue from the numerous white hairs with which they are covered. It is said to be found in several of the West Indian Islands, but I have only received it from Jamaica. *T. JAVANICUM*: This is a beautiful species from Java and various other islands to the Indian Archipelago; the fronds, produced from a tufted caudex, are from 3 inches to a foot high, pinnate, and of an intense deep sea-green colour. *T. PLUMULA*: This fine form was introduced from Demerara by the Messrs. Low, of Clapton, about the year 1863. I have not seen it in any other fernery, and am not aware if it is still in cultivation. If not, it deserves to be reintroduced as speedily as possible. The fronds are about a foot long and 1½ inches wide. It is considered by some to be a variety of *crispum*, but it is quite distinct from that plant. *T. SINICUM*: This is one of the very prettiest species for draping a piece of rookwork or clothing the stem of a Tree-Fern. The rhizome is slender and wiry, fronds pendant, from 3 inches to 9 inches long, and an inch broad; the texture is almost transparent, bright cheerful green in colour. It is plentiful in Trinidad, and is also found in some other of the West Indian Islands as well as Tropical America. J. J.

3200.—**Greenhouse Ferns.**—To those you already possess you might add *Pteris argyrea*, *P. cretica nobilis*, *Lenaria Gibbs*, *Micropolia himalaica*, *Nephrolepis distachya*, *Faraceae*, *Phlebodium aureum*, *Adiantum ornatum elegans*, *A. decorum*, *A. acutum*, *A. thuctum*, *Cyrtium foliosum*.—E. H.

3123.—**Anemone coronaria** from seeds.—If the seeds are sown in March some of the plants will bloom next autumn and winter. Sow thinly in well pulverized soil, covering lightly.—E. H.

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free, 6d.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1891, forty-two vols., price, cloth, 430 12s.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volume. Price 5d.; post free, 6d.

"Hardy Flowers."—Giving descriptions of upwards of thirty hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Revised Edition. Price 1s. 6d.; post free, 1s. 9d.

ORCHIDS.

ORCHIS FOLIOSA.

This is a plant which I find many of my readers making sundry inquiries about, and apparently they wish to grow it. Now, there is nothing to prevent them doing so if they only set about it in a rational manner. Some writers affirm that this species is hardy, and that it will live in the open air planted out in a sunny corner. To this I cannot subscribe, although I do not wish to find any fault with the assertion; but I may here state that I have not been successful with it in the neighbourhood of London, although I had lots of our native Orchids in my garden, and these grew and did well. The present plant, however, is a native of the Island of Madeira, and I have had a letter from a friend who is staying there. He writes me that "it is very hot here," and this would lead one to the conclusion our winters are not congenial to it, and I may here remark that at the time I was trying to establish this plant in the open-air garden without success I was very successful with it as a pot-plant under cover, and in this manner I would advise my readers to try it and to grow it, when they will find it thrive and flower most profusely. A cool-frame is the best place to winter it in, but not cold a one; in such a place I have found the temperature fall as low nearly as in the open, and much lower than it does upon any occasion in the island of which this plant is a native, and, therefore I do not think it is well to subject it to greater depths of misery than is necessary. The foliage is ample, and the plant grows up to 2 foot or more in height, and produces dense racemes of its showy flowers towards the end of the month of May and the beginning of June. The usual colour of the bloom is a beautiful rich brownish-purple, with darker spots; but I have had the ground colour of the flower of a soft rosy-lilac with dark spots, and I have even had this plant develop an albino form; but I must say I do not like the pure-white flowers so well as the colour of the typical plant, but this is enough to prove the variability in the colour of this species. This *Orchis foliosa* should not be potted in the manner of the majority of Orchids; but it should be potted in a similar manner to a "Geranium," the pots being well and properly drained, using them of good average size, and for soil use a mixture of good turfy, light, yellow loam and some rich and good leaf-mould. Soon after this article will appear they commence to grow, and during this season it likes a liberal quantity of water; the drainage being in perfect working order, it soon passes away, and if the bulbs are strong enough flowers will be produced in due season; but the plants will require to be kept from the catching spring frosts. After the flowers are over water must be given more sparingly until very little is given; but I do not recommend drying them entirely, and soon after the new year they should be potted and placed in a quiet place until growth starts.

MATT. BRAMBLE.

CYPRIPEDIUMS.

A FRIEND sends me a few flowers for naming, and he has adopted a very good plan—that is, in sending a leaf with each bloom. No. 1 is a very good form of *C. politum*, which was long ago obtained by Mr. R. Warner, of Chelmsford; but it would not appear to have entered the heads of the early raisers of hybrid Orchids the necessity of keeping a record of the parents, but there cannot be a doubt but what it was obtained in some way between *C. venustum* and *C. barbatum*, but I could not venture a remark upon which was the pollen-bearing parent. This is a variety that is well worthy of recognition even at this day when we have such a host of hybrids. It is a good sized flower, and its colours are bright and cheerful, and its foliage, which partakes much of the *venustum* character, is very ornamental. No. 2 appears to be a poor variety of *C. Swianum*, which I should advise you to destroy, and get another form of this variety. There are some *Swianum*s with a large and bold lip, the flower being good and well worth preserving. It is one of the early hybrids, and was raised by my old friend, Van Ouden, when gardener to Mr. Leech, at Manchester. No. 3 is a very bad form of *C. Hookeri*, evidently

near *Bollenianum*, a small flower, and is tinged with a slate-green. You will greatly add to the reputation of your collection if the place that knew it once knows it no more for ever, for I would certainly not keep it amongst the other showy kinds. No. 4 is, apparently, *O. euryale*, which is a handsome and good variety obtained between *C. Lawrenceanum* and *O. superbiens*. It has two good parents, and it partakes of both their qualities. No. 5 is *enpencilare*, another excellent hybrid raised between *C. barbatum* and *C. superbiens*. It is a fine, bold flower; another instance of the early hybrids maintaining their position. And No. 6 is *C. javanicum*, having a greenish flower of no beauty, and which I do not advise you to keep for any other reason than its bright, variegated foliage. All these plants will now require to be spotted or resurfaced, so as to have everything neat and tidy when the days of March set in, when we may expect some hot, bright days; so be sure that the plants are got up into position ready to let down over the plants should occasion arise, remembering that saving from scorching in the spring saves the appearance of the entire collection for at least the entire year. More especially is this the case with *Cypripediums*.

MATT. BRAMBLE.

EPIDENDRUM VITELLINUM
GIGANTEUM.

I AM in receipt of a fine branching spike of this plant from "Leeds," and it is the form which I have seen called *giganteum*. The writer says "The plant has been growing stronger for these two years, and now is flowering beautifully." Well done! my friend, you have a very magnificent variety, one well deserving every attention, and the fact of its having gone on so well with you speaks well for your treatment being just what it requires. Now, some have asserted that this plant could only be grown well by those living near the sea. Now, Orizaba, which is the district in Mexico where this plant is found, is not near the sea; and I have seen it in a worse state in collections that have been near the sea than I have ever seen it; and although I do prefer these maritime spots for Orchids, because of the purity of the air, it is not this alone that is wanted by Orchids; and this particular species wants to be grown in a well-shaded house, and the moisture in the atmosphere must be well attended to. Leeds cannot lay claim to be influenced by the sea air, and my friend tells me his plants have been grown in the same house I selected for them a few years ago, and his cool-house varieties have been grown from my instructions, and I certainly have to commend him for the excellent spike of bloom he has now sent me up. It is now more than sixty years ago since the typical *Epidendrum vitellinum* was first found in Mexico, and it is over fifty years ago since the plant flowered in England for the first time; but some twenty-three years ago, Roezel sent the variety majus to this country from the neighbourhood of Orizaba, where we are told it grows in a temperature which seldom exceeds 70 degs. of heat at any time, and that during the growing season it receives a constant and daily wetting from the rains that fall, and that during the winter it is enveloped in fogs, and that frosts are frequent during the night for about three months, so that the plant does not appear to live in a state of nature under the most lovely and happy climes, and under cultivation it is a plant that does not require the sunshine upon it, although it should not be excluded from the light, and if the drainage is kept in perfect working order, water should be given it overhead daily with advantage, except through our three winter months, and then the plants should be kept in a nice, moist state, for I consider that dryness is, above all things, the great ruin of the plants, whilst the temperature of the *Odontoglossum-house* suits it admirably.

MATT. BRAMBLE.

COELOGYNE OCELLATA MAXIMA.

I AM in receipt of a fine spike of bloom of this very beautiful variety, by a friend from the neighbourhood of Salisbury, signing "B. T. M." and giving its name and how to manage it. Well, this plant was originally imported by Messrs. B. S. Williams, of Holloway, and

superior form to the typical plant. This species is tolerably plentiful on the Khasis Hills and in Sikkim at considerable elevations; but at what altitude the variety maxima occurs I am not aware, but it is a great beauty, and its raceme of flowers is more full, and the individual blooms are fully double the size of the ordinary form. These are pure white in the sepals and petals, and the lip also is of the purest white on the outside, the side-lobes on the inside being streaked with orange on the inside, and in the centre are several spots of bright yellow, margined with a red border. These flowers yield a delicious perfume, and they may be used either by cutting the spike and using the whole raceme either as a shoulder-spray or a wreath for the hair, or they may be wired singly for purposes of personal adornment. The latter method is the plan usually adopted, because it is the more economical, and, thus treated, the flowers last longer, and the plant will last in bloom the longer, always cutting them from the base of the spike first. With the above also comes a spike of *O. floccida*, which is a plant not to be mentioned in the same chapter with *C. ocellata* for beauty and usefulness, for in the first place the flowers give off an effluvia resembling a stable, which entirely prohibits them being used for adornment; but this is not perceptible when hanging in the Orchid-house. The sepals and petals are creamy-white, lip the same colour; the lip is white, marked with brown lines in the closed part, having a rich yellow stain on the front. It blooms very freely, but its malodorous properties entirely prohibit its use amongst cut flowers. Both plants may be grown together and treated in a similar manner. They should both be kept in the Cattleya-house, potted in well-drained earthenware pans, and these should be hung up near the glass. The soil these plants like is a mixture of good brown peat-fibre and chopped Sphagnum Moss in about equal proportions, and well mixed. During their growing season they like an abundant supply of water, but not too much, both to their roots and overhead, also from the syringe, and at no time of the year should the drying season be made to last too long, or to cause any amount of shrivelling of the bulbs, or changing of the colour of the leaves, for these plants do certainly show to greater advantage when their flowers are backed with their green leaves; therefore, the plants should be rested for a short time at the warm end of the *Odontoglossum-house*, and kept in a moderately moist condition.

MATT. BRAMBLE.

3058.—**The Winter Cherry.**—In reply to "L. E.," the seeds germinate best when sown as soon as possible after they are collected, and seedlings raised now will make good plants next year. Sow in the open, and the plants will appear towards the end of March, but autumn sowing is preferable. Prepare the ground in the usual way for seed, and do not get disappointed if it remains dormant for some time. Be careful to watch for mice, which are very fond of the seed. The Winter Cherry is a fine old garden plant, and is a native of Western Europe, also Central Asia, even to Japan. Clumps of it on the border in loamy soil, not too heavy, and an open situation are very attractive during the winter months when the stems are hung with the Chinese-lantern-like fruits, or rather calyxes, as it is these that give beauty to the plant, being inflated, and bright-orange in colour. It is astonishing what a length of time they remain in beauty when out for the house. I have some in vases that have been there for over a year, and they are still bright. In the case of large gardens a good bed of Winter Cherry is useful, and has an attractive aspect through the winter months, whilst the stems may be cut for the house when required. A very easy way to increase stock is by division of the roots, and we may mention that if its stems are much in demand for decorations, a reserve bed would be an advantage.—C. T.

3115.—**Coal-ashes on a clayey soil.**—Certainly not. Your gardener must have wireworms, or, at least, "maggots," in his brain to imagine such a thing. Pure, fresh coal-ash is the best dressing possible for such land as yours, and the more you can put on and work into it the better.—B. C. R.

3123.—**Geraniums bursting.**—I expect you grew your plants too strong; but the soil has a great influence in that respect, and some varieties are persistent podurata. It is not good culture to keep the old plants unweeded, but you will probably find the flowers less ready to burst. Do not manure them much.—B. C. R.

FRUIT.

3199.—**Vine in a pot.**—Give a top-dressing, 2 inches thick, three parts of loam and one part of bone-meal, to the surface of the pot. If this be already full of soil place some pieces of turf around the inside edge of the pot, so as to admit of the top-dressing being laid on the surface roots. Pinch out the point of the side shoots two joints beyond the first bunch that forms on these, allowing the leader to extend, if it has not already covered its allotted space. Supply the roots freely with tepid water, never allowing them to become dry for even a short time. When the bunches are in bloom give the stem of each a gentle tap to disperse the pollen, assisting fertilization of the flowers. Directly the berries are the size of small Peas they should be thinned, so as to allow space for each to swell to their fullest size. After thinning abundance of warm liquid-manure will assist the swelling of the berries. This may be given every alternate watering, but not too strong; if from the ordinary farm-tank, about the colour of brown brandy will suffice.—S. P.

— Presuming that this is a fruiting Vine, and that the shoots have made some growth, they should be trained as near as possible to the glass roof of the house, but so as the leaves do not come into contact with the glass. When it is stated that the temperature is from 50 degs. to 60 degs. this must be taken to mean that 50 degs. is the minimum or night temperature, and 60 degs. the maximum or day temperature. The temperature may at once be increased to 55 degs. as a minimum, and in two or three weeks to 60 degs., with proportionate rise by day. When the Grapes are set the minimum temperature may be 65 degs.; but if this is difficult of attainment 60 degs. will be enough. When it is seen that fresh roots are being formed, a surface-dressing of loam and rich manure in equal portions will be beneficial. The roots will push into it freely, and, besides this, weak liquid-manure may be applied twice a week. Some attention is required when the Vines are in blossom. The atmosphere of the house ought to be drier at that time, and the temperature should be at least 65 degs. at night. Gently shake the bunches daily to distribute the pollen, which will fly off in a cloud of golden dust. Thin the berries out about ten days or two weeks after the fruit is set. The Black Hamburgh is a free-setting variety, and the best of all Grapes for pot culture.—J. D. E.

3138.—**Blackberries in an orchard.**—You might grow some of the American Blackberries, such as Wilson Junier or the Cut-leaved Blackberry (*Rubus laciniatus*), which is an excellent variety. It grows strongly, and bears clusters of large, rich, black, finely-flavoured fruit, whilst the leafage is very ornamental, being cut like Parley. A fairly good soil will grow Blackberries well. These are not difficult to succeed with, and in the position mentioned should do well. I have seen the Cut-leaved kind bear a quantity of fruit in apparently very uncongenial spots.—C. T.

3204.—**Pruning an Apple-tree.**—Whatever pruning is needed do it all at once, rather than leave it until next autumn. The kind of tree will determine the extent of pruning required. If it is a standard, pruned a bush, or a tree, provided there is abundant space for its branches to extend, do not shorten these back, except where the young shoots are 18 inches long; then

take off 2 inches of the point to induce the back eyes to break into growth. The main aim in pruning is to allow a free circulation of air and sunlight to the middle of the tree so as to induce the branches and fruit-spurs to mature their current year's growth to admit of their giving a full crop of fruit annually. Remove all shoots that are not needed to fill up a space. In the case of trees growing in a limited space, the points must be shortened back to within a few inches of the old wood as the allotted space fills up, all side growths from the main branches should be cut back to within an eye or so of their base. The salient points to observe in pruning Apple-trees is to fill up the allotted space with the main branches, and afterwards to see that these are not overcrowded by useless growth. Maturity of the branches is the one object to aim at.—S. P.

OUR READERS' ILLUSTRATIONS: A pot Vine for the table. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. J. Nash, 1, Chapel-street, Bathampton.

— A tree that bore 5,000 Golden Pippins was well worth looking after, and should not have been neglected. How it should be pruned now it would be difficult to say without seeing the tree. It must be an old tree, and probably make but little young wood. In that case the pruning should consist in thinning out the wood when it becomes too much crowded. It is getting late now to prune, but any pruning absolutely necessary might yet be done. If there is much young wood some ought to be thinned out, and that remaining should be shortened a little.—J. D. E.

3023.—**Mildew on Grapes.**—This parasite is very troublesome sometimes in vinerias, and usually appears when the Vines are in an unhealthy condition, owing to badly drained borders or perhaps unskillful management. If the borders are well drained, and the Vines are otherwise well managed, mildew may be kept out altogether if the rods are well painted

in winter with a sulphur mixture. If mildew appears upon the leaves, paint the hot-water pipes with flowers of sulphur, stirred up in soft soapy water. If the pipes are well heated when the house is shut up, the fumes from the sulphur will destroy the mildew.—J. D. E.

— There is more than one cause for the presence of mildew on Vines. A damp, stagnant atmosphere will produce it as soon as anything. When vinerias are well ventilated without causing cold currents, and steady fires are kept going, there is no mildew. Mildew is not often troublesome in early houses; it is generally in late houses, in which the temperature is low and the atmosphere damp and stagnant. Possibly, also, the roots of the Vines may be in a sluggish state, and, though this of itself may not bring on mildew, yet it does predispose them to the attack. When mildew appears dress the pipes with sulphur and keep up a brisk fire, and, if this does not suffice, attack the mildew with dry sulphur, dusting it on the affected parts and blowing or syringing it off afterwards. It will not be wise to cease the attack until the enemy is quite destroyed. At the end of the season, when the Vines are pruned, wash the canes with a strong solution of Gishurst emponnd, with a handful or two of sulphur thrown in, and limewash the walls, some sulphur being added to the lime.—E. H.

— This may arise from several distinct causes. A stuffy atmosphere, especially if cold and damp at the same time, will cause it, and the presence of a lot of pot plants in the house, particularly if these are not kept perfectly clean and in good health, often give rise to it. Again, a damp, badly-drained border, with heavy soil, will produce mildew in its worst form, and, lastly, admitting rushes of cold air by opening the ventilators on the windward side of the house when the wind is in the north or east, in the spring, often causes mildew by checking the growth of the tender foliage.—B. C. R.

3147.—**An outdoor Vine.**—A Grape-Vine trained over the front of a house is a pleasant object, and in good seasons, if the growth has been properly thinned and stopped, such kinds as Black Cluster and Royal Muscadine will ripen well enough for wine making, and occasionally for dessert. But if profit is the object, an Apricot or a good late Pear will pay better.—E. H.

— There will be no difficulty in growing a Vine on a south aspect in Salop, nor yet in obtaining plenty of fruit; but the trouble is, with such—summer I was going to write, but seasons will be the more

correct word—to induce the Grapes to ripen. Years ago we used to get delicious Grapes from Vines on open walls in Surrey, and even in Worcestershire, in the good old days, but it seems impossible now. However, much may be done by careful pruning, stopping and thinning the growths. The main rods may run either horizontally or vertically, but preferring the former, and the lateral growths must be cut back to about three eyes every autumn or early in the spring. Thin out the young shoots to one or two on each spur, and as soon as the branches can be seen stop the growth at one or two joints beyond it. The old Sweet-water, the Royal Muscadine, and the Black Cluster are all good outdoor Grapes.—B. C. R.

— The treatment of a Vine.—I should cut the canes back to 6 feet. You will get as many and probably better Grapes by reducing the length. I am assuming you want Grapes this year. If the permanent welfare of the Vine is considered cut back to the bottom wire, and do not let them fruit.—E. H.

THE KITCHEN GARDEN.

PERPETUAL SPINACH, OR SPINACH-BEET.

This is a most excellent and useful vegetable, which can be had all the year round by making sowings at three different times—one in April, one in July, and another in September—devoting

Fig. 1.—White-leaf or Spinach-Beet.

ground to it according to the demand. The Perpetual Spinach seems to grow luxuriantly on any soil and at all seasons of the year, and being a gross feeder, one can give the plants a good quantity of liquid or other manure. Often, in very hot, dry weather, the round-leaved or summer Spinach is liable to run early to seed; therefore, it produces but few leaves, and those of only second quality. The perpetual sort, on the contrary, grows well in hot weather; and, by feeding the plants freely with artificial manure, one is able to get from the spring (April) sowing alone a good supply during the summer and autumn. The second sowing must be made early in July, in order to give the plants time to get well established before winter, and from these one is able to have a good supply, in proportion to the size of the piece of ground devoted to the crop. The September-sown lot comes in well in early spring. This Spinach is exceedingly hardy, and often, when the ordinary prickly-seeded winter Spinach is killed, it survives the winter unscathed. Ground for this Spinach is either dug deeply or, better still, trenched, working into it, at the same time, plenty of rotten manure for the roots to feed upon. The seed may be sown broadcast upon the beds or in rows, as they afford a better opportunity for keeping the ground free from weeds, and if need be artificial manure can be sown between the rows, hoeing it in deeply with a draw hoe. I find superphosphate of lime, or bone-meal, one of the best manures for Spinach; it seems to invigorate the plants in a very short time after being used. Liquid manure from the farmyard is, however, quite as good, only it requires to be oftener used during the season. I find two good dressings of bone-meal to carry a crop on for six months. The kinds best worth growing are the following—

WHITE-LEAF, OR SPINACH-BEET (Fig. 1).—The leaves of this variety when true are very numerous, broad, slightly undulated, and of a very light or yellowish-green colour. The leaf stalks are somewhat larger than those of the Beet-root, and are of a paler colour than the blade of the leaf. A most excellent kind.

SILVERY SPINACH, OR SEAKALE-BEET (Fig. 2, page 9).—A very fine and good kind, with large broad leaves, which are very much undulated, half-erect, and remarkable for the size of their stalks, often 4 inches broad or more, and mid-ribs. This variety has, when cooked, a very delicate acidulous taste. The blade of the leaf may also be used like the first-named kind.

WHITE CURLED SWISS SPINACH-BEET (Fig. 3).—This is almost as vigorous and productive a variety as the preceding one, with leaves equally white, but crimped and curled in a remarkable manner. The stalks and mid-ribs are not so broad as those of preceding kind, but they are of quite as good quality.

3124.—Cabbages "clubbing."—No amount of ashes will prevent Cabbages "clubbing" on infected ground. This cause of Cabbages, &c., "clubbing," is that they are attacked by one of the parasitic Slime Fungi (Plasmodiophora brassicae), which is very difficult to eradicate. Burn every scrap of the Cabbages you can find, and do not grow any plants of a similar nature on the ground for two years. You may in this way stamp it out.—G. S. S.

3182.—Celery bolting.—Early sowing, standing starving about in pots or pans before pricking off, or checks of any kind will do it; and it may proceed from the seed being saved from a bad strain, or, in other words, there may be a predisposition in the plants to bolt. It is very rare for late Celery to bolt prematurely. This shows that the chief cause of bolting is a check during the early growth under glass, though I have known Celery to bolt from the use of strong forcing manure. The manure for Celery should be thoroughly decayed.—E. H.

The cause of Celery running prematurely to flower is by its experiencing a check, probably in the very early stages of its growth. I have observed that when I sowed the seed in boxes, and caused it to vegetate in a hot-house or a hot-bed, and gradually inured the plants to the open air, I generally had a large number of such plants run to seed; whereas if it was sown in a border out-of-doors, and the plants were carefully pricked out, and were never allowed to get very dry at the roots, I had no plants bolting amongst them. I am sure, therefore, if the seeds are sown out-of-doors, and the plants are grown on well afterwards in good soil, there will be little or no trouble with plants bolting. Celery grows naturally in ditches and marshy places, and must be well watered in summer.—J. D. E.

3195.—Tomatoes for market.—The plants do well in good-sized boxes, and I have both seen and grown some excellent crops in this way; but the simpler, as well as neater, plan is to plant them out. Where the soil is of a suitable character—i. e., a moderately light loam of good quality and fairly well drained, a very common way is simply to plant the Tomatoes out in the floor of the house, the ground having been previously dug over and manured slightly. Otherwise, a bed should be prepared for the plants, and, on the whole, it is better if this can be raised a little. Put a layer of broken bricks or clinkers in the bottom for drainage, then some rough turf, littery manure, or the like, and, lastly, 9 inches to 12 inches of soil, which may consist of any rather light loamy soil (good garden mould will do), mixed with a little (about a sixth part) of well-decayed manure, some burnt earth, and a dash of soot. In a single row the plants may be 12 inches to 15 inches apart, according to the variety; but if three or more rows are placed together, the plants should be at least 18 inches apart, with 2 feet between the rows; nothing is gained by crowding them in any case. Ventilate freely throughout, and give no shade. Water should be given rather sparingly until there is a fair quantity of fruit set and swelling, then give more and let the plants have some liquid manure as well.—B. C. R.

—Large growers generally plant out in the borders, and when the house is given up to the Tomatoes the plan is economical, and answers well. For very early work, boxes or large pots are very suitable, and are, I think, preferable.—E. H.

3203.—Seed Potatoes.—Stand the sets on their eye-ends upwards in any cool light room. If placed in shallow boxes they are more easily moved about than when laid loose. The sprouts ought to be half-an-inch long at planting-time; if they are an inch long no harm will result providing they are robust, not drawn up weakly. It is a mistake to plant Potatoes with many sprouts on each; two good ones are sufficient, more only crowds the growth, preventing a due development of the stems and leaves which favours small tubers and disease. Two strong shoots are much better than double the number of weakly ones. Four inches deep is quite sufficient covering for them when planted. The best method is to dig the ground and plant at the same time. The soil is left free and loose between the rows, offering no obstruction to the roots, which ramble a long way in search of food. When the haulm is 6 inches high draw the soil on each side up to the stems, not in ridges

fashion, but leaving the soil close to the stems lower than that on each side of the row. If done in a complete ridge, matting close to the haulm, the water from rain runs off into the trench, the plants being thus deprived of the necessary moisture. Early varieties of the Ashtop section need less space than either mid-season or late kinds, 2 feet for the former between the rows, the sets 1 foot apart. The other kinds 2 feet 6 inches from row to row, and 15 inches between the sets. Nothing is gained by crowding them.—S. P.

The best way to "sprout" the sets is to lay them out eye-ends uppermost, in shallow boxes and place those in a light and rather warm place for, say, a month before being planted. The Jersey growers place all their seed Potatoes in flat boxes of which the ends are made rather higher than the sides, with a strip of wood nailed across for a handle. This is done in the autumn, as the crops are lifted, and the boxes are carried indoors and stacked up in tiers for the winter; in this way a certain amount of light and air reaches every set. In the spring the boxes are again carried to the fields, and the sets taken one by one and placed directly in the furrows, with the shoot or "spear" intact and unbroken. 2. The right depth is about 5 inches on heavy land, 6 inches for medium, and 7 inches for very light soils. 3. Earth up slightly when the growth is about 3 inches high, more—as high as you can—when it has grown another 6 inches. 4. Eight or nine inches apart is the proper distance for the early short-haulm kinds, and 12 inches for the late tall growers. The distance between rows should be 2½ feet, and 3 feet to 3½ feet respectively. It is a great mistake to crowd Potatoes in any way.—B. C. R.

3189.—Raising Tomato-seeds.—Make up a slight hot-bed, say about 3 foot high at back and 2½ feet at front, and sow the seeds thinly, broadcast if many are wanted. They come very strongly treated in this way, the lights being taken off to harden the plants. As soon as the plants come up, whenever the weather is mild, they may be sown in pots, and the plants pricked off when large enough, but this plan causes more trouble, and there must be a little warmth to start them. After potting off warm covering will be necessary at night.—E. H.

—If you wait another three weeks before sowing your Tomato-seed, the best part of the summer will be over before the plants begin to produce any ripe fruit. I should advise you not to lose a day in getting the seed in, as with our short summers and cold, wet autumns none but early plants are worth the trouble they entail, certainly for planting out-of-doors. Sow the seed in a pan or box of light, sandy soil, with good drainage, and place it in a frame or house at 60 degs. to 65 degs. A frame over a mild hot-bed is a good place; but the heat must not be too strong, and much steam is injurious.—B. O. R.

3103.—Forcing Rhubarb.—It is not a difficult matter to force Rhubarb, and it may be readily accomplished by packing the roots together under the stage of a warm house. Surround the roots with soil, which must be maintained in a moderately moist condition. You may also force the roots in a deep pit or darkened frame, having a bottom-heat of about 85 degs. to maintain a sufficient heat. This can be gained by having fermenting matter composed of about equal parts stable-litter and leaves. Hawks's Champagne variety, which was recommended recently for general cultivation, is suitable for forcing, so also is the variety Early Red. Rhubarb may also be forced where it grows by covering the crown with a large pot and stable manure or fresh-collected leaves. A market gardener of my acquaintance forces a lot of Rhubarb in an ordinary plant-house where he keeps bedding-plants during the winter, the temperature in severe weather being kept at about 45 degs. In the centre of the house there is a stage, and beneath this is placed the Rhubarb. A succession is kept up by removing the crowns as soon as they have done duty and bringing in a fresh supply. The roots, when forced, are packed away in a sheltered spot, soil thrown amongst them, and covered with a little straw for protection from frost. If you have only a small plant-house you may get early Rhubarb by this plan, as the temperature is not

CHRYSANTHEMUMS.

3210.—**Chrysanthemum culture.**—The only stimulant advisable to syringe over the leaves is scot-water, and I do not know for certain that much benefit is likely to accrue from the practice. There is an idea that scot acts as a corrective of pale coloured foliage. Want of strength in the stems and robustness, coupled with deep-green colouring of the leaves, is owing to some cultural defect at the roots; although in some localities the leaves are always much paler in colour than in others, owing possibly to the constituent parts of the natural soil not being in itself suitable to Chrysanthemum culture. The best remedy for paleness of the leaves is keeping the plants rather on the dry side at the roots; too much moisture is detrimental, as it causes a check to the younger roots, preventing them from fulfilling their proper functions. Although Chrysanthemums are moisture-loving plants, they can have too much under some conditions, and these should be alluded to. Very often in the first stage of growth, some sorts, especially *Boule d'Or* and *E. Molyneux*, will assume a pale tint of colouring of the leaves. If the soil in the pots is kept drier than hitherto, a change will soon be apparent. This is the best test that can be applied. The strength of the stems in any stage of growth depends very much on the state of the cuttings at the time when they were taken and their subsequent treatment. If these are weak at first, rooted in heat and grown on in it afterwards, without a sufficiency of light and fresh air, weakly plants must be expected; no amount of manure or after-treatment will prevent this. Chrysanthemums do not require heat at all, only sufficient to keep out frost. A cool-house is the best place to strike the cuttings in and cold frames afterwards to stand them in until all danger of frost has passed. An open, sunny situation out-of-doors, secure from north and south-west winds, suits them the best until the end of September, when they should be housed. During hot, dry weather, while the plants are outside they will be benefited if the leaves are thoroughly syringed twice a day, early morning and in the evening, but with clear water. A compost of two parts loam, one of leaf-mould or half-decomposed horse-manure, with sufficient sharp silver sand to make the whole porous, is what the plants enjoy during the early stage of growth. For the final potting add one more part of loam, and to every bushel of the compost add 1 lb. Innes' or Thomson's Vine-manure. If the soil is heavy and retentive of moisture, some finely-crushed charcoal or pounded oyster-shells will be an advantage. Pots should not be too large. Those 9 inches in diameter afford sufficient space for the strongest growing sorts. From the cutting-pots the plants should go into those 3½ inches in diameter, then into 5½-inch ones, from these into the flowering-pots. Good drainage is absolutely essential to success. Stimulants are not needed until the pots in which the plants are to flower are full of roots. Liquid-manure from the farmyard tank, diluted to about the colour of brown brandy, given three times a week, is good. Falling this, place some cow or sheep-dung along with a little scot in a tank or tub of water, putting the manure in a bag to prevent its mixing bodily with the water, which would choke the water-passage. Even falling this, use as directed some of the many artificial stimulants, never exceeding the strength recommended.—E. M.

3211.—**Japanese Chrysanthemums.**—The following varieties will be found suitable if the plants are started early and well managed throughout the whole season: *Lady Selborne* (white), *Mme. C. Desgrange* (white), *Mrs. Hawkins* (yellow), *M. W. Holmes* (crimson, bronze tips), *James Saltar* (clear lilac), *L'Affre-caine* (crimson), *Bouquet Fait* (pink), *M. E. Pynaert Van Geert* (yellow, striped red), *Isidore Keral* (rosy-lilac), *Felix Cassagneau* (bright-orange, flamed salmon-red), *E. G. Henderson et Son* (golden-red, crimson reverse), *Bonquet Festival* (deep-rose, reverse of petals silver), *Phœbus* (yellow).—E. M.

3206.—**Sinking a well.**—An artesian well has to be sunk to a great depth, and as special machinery is required for boring it is a very expensive matter, and, moreover, the attempt is not always successful. If there is water at 12 feet or 15 feet below the surface the

better plan will be to employ a man to dig an ordinary well, and see that he goes down till a good spring is struck. As regards pumps, it all depends upon what quantity of water is required; pumps of different powers and makes are to be had at all prices from a few shillings to a hundred pounds or more. I have rather a fancy for the triple pump, worked with a wheel and cranks—at least, where a large and continuous supply is required. Bear in mind that water taken direct from a well is generally unsuitable for all garden purposes, being cold and harsh, so that it would be advisable to have a large shallow tank into which the water can be pumped and lie in the sun for a day or two before being used. If the tank can be raised, and pipes laid from it to the different parts of the garden, the watering will become a very easy matter.—B. C. R.

HOUSE & WINDOW GARDENING.

FERNS AS PLANTS FOR THE DINNER-TABLE.

WITH the large increase in the numbers and varieties in most cases of such plants as *Crotone*, *Dreconas*, *Aralias*, *Palme*, and *Pandanads*, the mere fact of there being many kinds of Ferns which are also well suited for the same purposes seems in a measure to have been lost sight of lately—at least, if the plants usually exhibited at flower shows are in any measure to be taken as a guide to the most approved selections. Ferns certainly have escaped the notice of those growers who exhibit. My own inference, however, is that the usual run of plants that one meets with in such instances does not by any means embrace either the most comprehensive choice as to variety, or does it include sufficient variation in form and in the size of the plants. Ferns certainly are most convenient plants for dinner-tables when a good selection is made for the purpose. Those sorts are the best which can be grown to a good size in a proportionately small pot. Lightness of growth, both in the character of the fronds and as regards any undue excess of the same, are two points to observe in making a selection. Those plants only should be used which are thoroughly well established in their last shift; if pot-bound, all the better, the frondethus being more enduring so long as sufficient water is given the plants. Plants large enough for all practical purposes can be had in pots that do not exceed 4½ inches or 5 inches diameter inside, the lesser size being most preferable. The varieties that do not assume too dark a green in the fronds will be the most effective, particularly if the plants are rather large. Ferns of the hardier or greenhouse type are very handy for use during cold weather, when exposure of stove plants would involve some amount of risk. A selection of plants should be made for the purpose of table-decoration, the said plants being kept elevated upon pots above the surroundings; in this manner better all-round examples can be grown. Another good plan is to suspend them from the roof, standing the pots in pans to which wires are attached; thus the plants can be removed at pleasure. The following will be found a good selection for cool or temperate-houses: *Adiantum decorum*, *A. cuneatum*, *A. deflexum*, and *A. Capillus-veneris* *Mariosi*, *Asplenium flaccidum*, *A. lorum pumilum*, and *A. dimorphum*, *Lastrea lepida* and *L. potens*, *Leucostegia immersa* (in the summer-time being deciduous), *Pteris argyrea*, *P. cretica nobilis*, *P. cretica Mayl*, *P. serrulata major oristata* (the *Chiswick* variety, one of the best), *P. tremula* (a good old fern), and *P. leptophylla*. For the stove the following should be included: *Adiantum Farleyense*, *A. mundulum*, and *A. Collii*, *Asplenium ciutarium*, *Oymnogrammas* in variety, avoiding those of straggling growth; *G. Altoni*, *G. Lanchensis*, *G. peruviana argyrophylla*, and *G. schizophylla gloriosa* are a good selection; *Onychium auratum*, *Lomaria gibba*, and *Phlebodium aureum*. F.

FOLIAGE PLANTS FOR A PROPAGATOR.

Or late years foliage plants have become almost as popular as flowering ones, and certainly it is a great addition to the attractions of a room, a balcony, or conservatory, where the flowers look far better when set off by hand-

some semi-tropical groups of foliage plants. But those who have no glass, except a room propagator, may easily contrive to have a goodly collection of these splendid plants, raising them in early spring, and hardening them off carefully in a window until June, when they will grow best out-of-doors, whether in pots or in borders. *Ricinus* (*Gibsoni*), the *Bronze-leaved Castor-oil*, is one of the easiest to cultivate, and at the same time the most handsome, for its broad, richly-tinted dark leaves are a welcome addition to any group of plants. Each seed should be sown separately, in a very small pot, for this is not a plant which is easily moved while very young, although a shift is not difficult when the plants are about 4 inches high, if the soil is not disturbed, but simply placed in a slightly larger pot, with more compost added and thorough drainage. As drainage is most important for the health of all plants—except those in thumb-pots, which require but one crock at the bottom—it may be well to explain the process here. Cover the hole with a piece of crock, with its concave side downwards (it is seldom quite flat, being a bit of broken flower-pot), and over this arrange three or more smaller pieces in such a way as to prevent the soil choking the drainage. These should be covered by a small bit of dry, clean Moss, and over all may be sprinkled a teaspoonful of scot, which has the double duty of nourishing the lower roots and keeping out insects. A little fresh compost laid over the Moss will receive the lower roots of the plant to be shifted, and more compost must be shaken or worked down between the ball of roots and the sides of the pot, leaving from half an inch to an inch of room at the top (after firmly pressing the plant into the new soil and making all neat) for watering purposes, so as to secure a proper supply. *Ricinus* needs rich soil, as it grows large, but not as a seedling; spent soil—i.e., that turned out from potting other plants—and sand will do for the first soil for the seed, gradually adding leaf-mould, with a little scot and sand, and eventually old hot-bed stuff to the compost used at each repotting, till in June the plants are in large pots with rich soil, when they will take plenty of water daily, and can be used as handsome decorators for the drawing-room or balcony. I. L. R.

3194.—**Leaf-mould.**—The best leaves, both for hot-beds and also for mould, are those of the Oak, Spanish Chestnut, and Beech, and the worst are the Walnut. In a general way rake all up and cart them home, and they are all used in mixture with good results; but Oak, Beech, and Elm-leaves predominate.—E. H.

!— I should be afraid to say what leaves are of no use for potting purposes, for in my experi-

Fig. 2.—Silvery Spinach or Seakale-Beet. (See page 8.)

ence of over forty years I have used the leaves of all sorts of deciduous trees mixed together. The leaves I prefer are those of the Oak, Beech, Elm, Sycamore, and the Common Plane-tree. I have also used the Spanish Chestnut leaves and have found them excellent, but the Horse-Chestnut, although the leaves are all right, are usually mixed with the nuts of the tree, which are productive of fungus. Oak-leaves are the best to mix with manure for a hot-bed, but any other leaves may be used.—J. D. E.

3201.—**Boards by the side of beds.**—Dress the boards with hot tar before putting them, or else paint them well with creosote first, and, if desired, with ordinary green; or other paint afterwards.—B. C. R.

NOTES ON THE CULTURE OF THE
BEGONIA.

The time has again come round for us to begin to think of preparing for our summer feast of these flowers. Those who intend to sow seed to have hubs to flower this next season must as soon as possible make preparation for it. The first thing to do is to get some good leaf-mould, with a little loam sifted very fine, mixing with it some silver sand, having some well-cleaned pots crocked, 6-inch ones being the best, filling them half up with a layer of Moss or sittings at the bottom. Then fill up to within an inch of the top of the pot, not pressing too firmly. Then water this thoroughly with boiling water, given through a fine-rosed pot. This will kill insects or weeds. Then let them drain well, after which sprinkle the seed evenly over the surface; then place a piece of glass over this, darkening the same with paper. This saves covering, and the seed will germinate better, placing the pot in a hot-bed heated to about 75 degs. In ten days' time you will find the seed begin to grow. As soon as it does this remove the paper, but leave on the glass. In about four days the seedlings should be well up. It can then be moved to a warm place near the glass. If the pot becomes dry it must be soaked, just letting the water appear, but be careful for it not to touch the seedlings, or they will damp off. As they grow tilt the glass up a bit with a little stick until they are hardened enough to remove it altogether. Be sure to keep all sun from them. They will soon get large enough to be pricked off. The soil for this operation should be the same as before described, only using shallow boxes or pans, taking out the little plants with a small stick, and put it in the place prepared. They should then have a sprinkle over and be put in a warm, shady place, and they will soon begin to grow away. They must never be let become dry. As soon as they are large enough they can be potted into small pots, using a little more loam and sand with the soil. As soon as ever the plants want a shift, they should have it, only with these shifts a little bone and charcoal should be used. Six-inch pots will be plenty large enough for the plants. The first year some will not require pots quite so large. While flowering, all the best should have special marks allotted and be propagated. This is to be done by means of cuttings. The little shoots should be taken which come up, not cutting too near the bulb, inserting them in Cocoa-nut-fibre or leaf-mould in bottom-heat. As soon as rooted they must be potted in light soil and kept growing so as to get good sized tubers that will keep through the winter. In growing specimen plants for show, it is necessary to select the short habited plants which flower freely. They must be started about February and grow on well, using good rotten loam and manure mixed, some charcoal and bones, having them kept in a shaded house heated to about 55 degs. by night. The plants should be sprinkled with a rose on fine mornings. On no account let them become dry, and when the plants have filled the pots they should have root-water alternately. As soon as the shoots are long enough they should have a neat stick and be tied. There are two classes to see and grow. If you want them for specimen plants select the dwarf, free-flowering ones, good types of which are Livingston, Mistress French, Sir Noel Paton, &c. For cut blooms for show the larger the better—Harold, Triumph de Nancy, Dr. Feltz, &c. G. H. H.

3100.—A rare Grass.—The Sea Reed (*Paspalum arenaria*), known also as *Ammophila arenaria* and *A. arundinacea*, is a common Grass in many parts of Scotland, and also in England, and I cannot conceive why "Robin" should consider it a "rare Grass." It is not of any agricultural value, as no cattle touch it; but it is found very valuable for blinding the drifting sand on the seashore. It also obtains the name of Marrum Grass.—J. JARVIS.

2995.—Cleaning moral.—This is a question quite outside of plant growing; but, having had a good deal to do with this, I have found the very best plan to do it is to suspend it upside down in a copper full of boiling water; the boiling water will remove the dirt from it, which falls to the bottom of the copper. It may require putting into several waters before it becomes quite clean; but it will clean it far before any brushing you can give it.—J. JARVIS.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will appear in the best manner, and will appear in our issue in GARDENING ILLUSTRATED.

TREES AND SHRUBS.

MOCK ORANGE (PHILADELPHUS).

While *P. microphyllus* is the best of the small-growing kinds, this occupies a similar position among those with large blossoms, and it is certainly one of the finest flowering shrubs to be met with in gardens. The individual blooms are a couple of inches in diameter, pure white, and with comparatively little scent. This forms a rounded mass from 6 feet to 12 feet in height, according to the soil and situation in which it is growing. There is a variety of this (*luxus*) less in stature and of a more open style of growth than the type. *P. speciosus* is now regarded as synonymous with *P. grandiflorus*. The planting season not being over yet, the claims of this Mock Orange for a place in any garden should be duly considered. B.

3191.—Hardy evergreen shrubs.—The first three named in this list are flowering shrubs, and grow beyond 5 feet high: *Arbutus Unedo* (Strawberry tree); *Berberis Beali*, flowers to February, blooms very sweet; *Ligustrum japonicum*. The next three grow tall, and are simply evergreen, but of handsome appearance: *Cupressus Lawsoniana*, *Juniperus chinensis*, and *Thuja Lobbii*. The first three of the next list are flowering kinds: *Olearia laevis*, *Laurustinus albus*, *Berberis Aquifolium*; and the remainder are remarkable for the hearty of

A Mock Orange in flower

their foliage, and remain a little over 3 feet for many years: *Aucuba japonica*, *Rotinospora plumosa*, and *Holly Golden Queen*.—S. P.

The Holly, either green or variegated-leaved varieties, may be selected, *Rhododendrons*, *Aucuba*, and not forgetting *A. Mascula*, which bears pollen, to be planted, therefore, to induce a show of berries on the fruit-bearing kinds. *Bambusa Metake*, a beautiful and quite hardy Bamboo, strikingly handsome when well-established; *Berberis Darwini*, *Euonymus* in variety, *Elmagnus japonica variegata* or *macrophyllus*; *Olearia laevis*, which flowers early in the autumn and makes a compact bush; *Veronica Traversi*, a fine bush, the flowers delicate-mauve, and produced freely towards the autumn; *Aralia Sieboldi*, useful for its handsome foliage; *Mahoeia aquifolia*, and *Yuccas*. All are hardy, though perhaps the *Veronica* may get touched in severe weather. The above forms a selection of interesting shrubs, a fair proportion flowering freely.—C. T.

The following are all very hardy:—Back row: *Holly Hodgkiss*, *Holly Golden Queen*, *Lawson's Cypress*, *Berberis stenophylla*, *English Yew*, *Thuja gigantea*. Front row: *Berberis Aquifolium*, *Aucuba japonica*, *Box (Golden)*, *Escallonia macrantha*, *Osmanthus ilicifolius*, *Tree Ivy palmata*. If the soil is suitable for *Rhododendrons* several of these would be beautiful.—E. H.

3111.—Nettles in a shrubby, &c.—There may be other nettles; but the usual plan is to keep cutting them down as fast as they appear. This gets rid of them in time, if one cannot thoroughly overhaul the soil and dig them out. Persistently cut them down, and the practice will prove effectual in the end.—C. T.

3110.—*Clematis montana*.—The *Clematis* is a varied family. Some of its members bloom upon the wood of the previous year's

growth, others upon that of the current season. A knowledge of their habits in this respect, therefore, is most essential to prevent mistakes in pruning. *C. montana* flowers upon the wood of the previous year, and therefore anything like severe pruning should be avoided now. My plan has always been to thin and disentangle the shoots at this time, and if the plant is upon a wall leave a fair proportion of them hanging somewhat loosely till flowering is past. The shoots are then wreathed to blossom. Immediately after flowering I give it a good pruning back, not minding the sacrifice of some young shoots, for, with the summer before it, the plant is sure to make enough growth for another season. If the plant in question is strong it may flower a little, but in any case do not prune it, and a vigorous growth should follow this year with abundance of bloom next.—A. H.

TWO GOOD SHRUBS.

There are two good shrubs that ought to be in every garden, as they afford so much enjoyment. The first is the *Wisteria Jasminea*, a cheerful, lovely thing, spreading its season of bloom over many weeks—in fact, months, for now again its shoots are wreathed in yellow stars, and an interesting point noticed is its recent recovery from the severe frosts that paralysed it for a time is that when grown in several different aspects it varies in the extent of its injury. Few plants are more easily grown, and happily it is widely known

and appreciated by many; but numbers of little gardens might find one or more nooks for it upon wall or fence where, at present, it is not grown. Although flowering at a time when its shoots are leafless it makes up by the very profusion of its blooms for any slight nakedness in this respect, and its welcome glow of colour is most cheering during the dullest, darkest days of the year. It is hardy, and thrives almost anywhere and in all kinds of soils. This season severe weather came suddenly upon us and caught the shrub in all its beauty of blossoms. Of course the open flowers fared badly, but the unfolded buds remained stationary during a month of frost, and now the mild days have permitted them to open. Not the least of its charms is its value as a cut flower, and shoots full of buds may be cut because they continue to open after the shoots are placed in water. In a cut state the branches are charming mingled with those of the bronzy *Barberry*, or the green branches of the *Ivy*. A pretty permanent effect of this description can be made by planting *Jasminum* and *Ivy* together. Those who want flowers for the house in quantity should make a point of growing this shrub, or need they fear to cut it, as the cutting of the flowering-branches, by judiciously thinning them, would be all the pruning the plants would need. The other shrub is pleasing more by reason of its sweet scent than from the effect it creates. It is the *Allspice* (*Chimonanthus fragrans*), and, like the *Jasminum*, after braving the vicissitudes of the winter weather that makes up our winter season, it responds to the first gleams of sunshine, and

fills the air around it with delicious fragrances. It does not, perhaps, accommodate itself to all sites and soils, but it is far from being fastidious, though flowering in the midst of winter, as it does, by affording it a sunny nook more enjoyment is obtained from it. The usual plan is to train it rather stiffly to the wall; but it should be allowed a little freedom, as by nature it is a self-supporting shrub. The wall is rather for shelter, and if the plant grows outwards, there is a greater abundance of twigs, which bear the flowers. In rich soil, and even when newly planted it is apt to be excessively vigorous. Further excessive pruning promotes strong growth, whereas the best flowering shoots are those of medium strength. Any pruning that the plant requires should be performed after flowering, but here again the need of the operation being anticipated at the flowering-season—the shoots can be cut when in flower, as the flowers last well, and two or three twigs of bloom are sufficient to scent a large room. A. H.

INDOOR PLANTS.

3050.—Plants from seeds.—You might raise annuals in a sunny window, or in a light position in the house, but then comes the trouble of transplanting, as seedlings are invariably sown too thickly, and must be pricked off into other pots. It means turning the house into a little garden. Say what kind of seeds you mean. I advise, however, that you only select such things that may be sown in the open as hardy annuals. The "game is not worth the candle," troubling about such matters in a dwelling-house.—C. T.

2998.—Heating a greenhouse.—You will require 30 feet of 3-inch pipe to heat the house according to the orthodox rule, but I do not place implicit faith in these calculations, as so much depends upon the position of the boiler and the arrangement of the pipes, as well as the position of the house, which, if much exposed, requires more piping than one that is well sheltered. In practice it is always easier to increase the length of piping a little. The equivalent of 4 inches for your space would be about 24 feet, according to the above rule.—J. C. C.

3069.—Tuberous Begonias from seed.—These Begonias can very well be raised from seed sown in a frame. If it can be safely protected from frost, sow the seed at once in sandy soil, but lightly covering it. If the soil is moist, as it should be, water will not be required for several weeks, providing the pan is covered with a square of glass, over which is laid some Moss to exclude the sun. Should, however, the soil become dry, water must be supplied. This is best done by placing the pan in tepid water, allowing it to gradually soak up through the drainage at the bottom. When the seedlings appear above the soil, remove the Moss to give the plants light to encourage them to grow strongly. When they are large enough to handle prick them out into other pans, pots, or boxes, in a mixture of half loam, leaf-soil, and sand, giving plenty of drainage. Keep the frame rather close at first and shade from bright sun. Keep the soil moist, always using tepid water. When the plants meet, they may be potted, if required for use in that way; if for planting in the beds, move them to other boxes and give abundance of air after the roots commence to run in the fresh soil.—S. P.

3036.—Treatment of Cyclamens.—Your Cyclamens should not be out of flower yet. When they are, do not dry off in the old style, but keep the plants growing steadily. They will not require so much water, and may be placed in a cool greenhouse until June, after which it is best to stand them in a pit, and give exposure day and night except during very hot weather, when they may have a gentle syringe, and partial shade during mid-day. You will then find the bulbs flower well another season. September is a good month to repot, and they may then be removed to the greenhouse again. Ericas, however, are very seldom grown well by an amateur, and as they require special and careful treatment I would not advise your attempting to grow it for bloom a second season.—P. U.

3051 and 3068.—Unsatisfactory Hyacinths.—Ever since I have had anything to do

with Hyacinths, and it is a good many years ago since I began my gardening career. Hyacinth bulbs have failed in the way this correspondent complains, and I expect they will continue to do so, for I know of no remedy to prevent it, as I have known them to do so under the most skilful management, and without any apparent reason. It is pretty clear, however, that it is badly matured bulbs that are the worst behaved in this respect, and which I believe is caused by arrested growth, or in other words the bulbs are lifted and harvested before they are ready.—J. C. C.

3026.—Violets in pots.—Much the best way to grow these is to cultivate the crowns or roots in the ordinary manner, and then to put them up during September. In most cases amateurs afford the potted plants too much heat—in fact, they try to force them, and Violets will not be forced, and give a satisfactory crop. You must keep the young plants, from the time they are started in April and May, free from runners. This will conserve all of the strength and conduce to good crowns, well set with flowers in embryo. Unless you secure this you cannot have such a quantity of bloom as you require.—P. U.

3027.—Manure for Begonias.—Almost any manure will do for these; but if of a natural class, it must be thoroughly decayed. For out-of-door beds, I prefer natural manures, but for pot work, guano, Standen's Manure, With's Plant Food, and other artificial compositions are rather better. Although the Begonia likes a free soil, it should not be composed of manure that during the process of decay leaves the soil too hoar or loose. Bone-meal is a good manure for mixing with the potting-soil. Other manures can be given in a liquid state, and preferably while the plants are in full growth. It is much best to use it weak and often than to concentrate the same amount of stimulants in two or three applications.—P. U.

3072.—White Azalea and Genista.—The Azaleas and Genistas will do admirably in a house from which frost is just excluded, and it would be better to allow the plants to open the first few flowers in the greenhouse. Such plants cannot thrive in the window of a dwelling-house. If the plants were put into the room windows before the flowers were near the point of expanding, perhaps they would open badly or not at all. As the plants look healthy they will most likely flower well. The Genista fragrans ought to be coming into bloom now. The flower-buds of the Azalea should be very prominent now.—J. D. E.

3121.—Sowing Calceolaria seed.—The seed sown now would not do much good to bloom this year. July is the best month in which to sow the seed, and good strong plants will be formed to flower the following season. Those not accustomed to sow Calceolaria seed must be very careful, as it is put up in very small packets, and the seed being so very small, a man with clumsy fingers may scatter it inadvertently. Sow on a level surface of finely-sifted soil, and sprinkle a little fine sand over the seed, scarcely covering it. Place a square of glass over, and shade from the sun.—J. D. E.

3150.—Management of a propagator.—There is generally this difficulty of an excess of moisture until one gets thoroughly initiated into the working of a propagator. There would be less moisture if you had only 1 inch in thickness of Cocoa-nut-fibre instead of 3 inches, and you would require less heat, and at the same time secure a more even temperature between the top and bottom—a difference of 20 degs., which you have now, is too much, and as I have already said, it is a waste of heat to have to warm a depth of 3 inches when a less thickness will answer the same purpose. There is really no difficulty in managing a propagator after you have overcome the trouble about the excess of moisture. I, however, advise you to reduce the quantity of fibre, and then take all the water out of the tank for a day or two until the covering of Cocoa-fibre gets pretty dry; you may then partly fill the tank with water, say about one quarter full, and when that has all evaporated you can add more according to the state of the fibre, whether it is very wet or dry; the more water it contains the longer the tank should be kept without water. If this advice does not help you out of the trouble kindly write again.

as I regard a well-managed propagator as being invaluable to amateurs for raising seedlings. In your case—as you have no greenhouse—the beginning of April will be soon enough for you to start sowing seeds. Meanwhile, you may experiment in the direction I have indicated with a few pans of common seeds—Mustard and Cress, for instance—so that you may learn how to regulate the moisture for choicer subjects.—J. C. C.

3152.—Forcing Malmaison Carnations and Gladioli.—Both these are forced in thousands and tens of thousands annually. They have been treated rightly so far, and might have been placed in heat earlier, but it can be done at once. It is always best in forcing any hardy, or comparatively hardy, plants to put them in rather early, and do not give them very much more heat than they had previously been growing in, increasing it gradually until the temperature reaches a minimum of 55 degs. to 60 degs. I would rather incline to the 55 degs. early in the season.—J. D. E.

3130.—Oleander not flowering.—This very pretty and sweet-scented plant is not a suitable subject for window culture; I am afraid you will seldom flower it in such a situation. Nerium Oleander makes growth freely during the summer, and produces bloom-buds in abundance; but unless you can afford a much higher and moister temperature than a window during winter and early spring I doubt if you will ever succeed in flowering it satisfactorily. The buds will drop off annually as you describe in your query. Get a friend to place it in a warm greenhouse if you cannot afford it such treatment yourself. It is a pity to lose the buds in this manner. Allowing the plant to get dry at the roots will also cause this.—P. U.

3151.—India rubber plant.—I should think that the plant requires repotting, or the soil has got in a bad condition. Either of these things would produce the appearance of the leaves you speak of. Give the plant first a good dressing of insecticide, sponging the leaves with the preparation carefully. Then, if the drainage in the pot has got disarranged, set it right, and, if necessary, repot the plant entirely, using a good loamy soil, in which a moderate quantity of peat has been incorporated. Make the whole fairly porous with sharp silver-sand. Place it in a warm-house, if possible, for a time until it has got established.—C. T.

3190.—Marguerite Carnations.—The seed should be sown at once, so as to allow time for the plants to attain a good size and develop plenty of flower-buds before the winter sets in. Sow rather thinly in a well-dimmed box of sandy loam and leaf-mould, making the surface moderately fine and pressing it together rather firmly. If you have only a small packet of seed a 6-inch pot will do. Lay a sheet of glass over the box or pot to check evaporation, and, unless the soil becomes really dry, give no water until the seedlings appear. Then remove the glass by degrees, and when large enough to be removed, transfer the seedlings singly to thumb-pots, or if they stand thickly and are too small for this, prick them out first into other boxes, and afterwards pot them, at first into 3-inch pots and then into 5-inch or 6-inch sizes in which to bloom. Some may be planted out-of-doors in June, and they will bloom freely in August and September. I like to grow at least part of the plants in pots, as these will continue to flower in the greenhouse up to Christmas, when the blossoms are very acceptable. They will, however, require the aid of a little occasional stimulant in the form of liquid-manure of some kind, and should also be kept near the glass in a temperature ranging between 45 degs. and 60 degs., with air on all favourable opportunities. Good sandy loam, with a fourth of decayed manure, grows these plants well, and it should be pressed firmly together.—B. C. R.

3180.—Making a hot-bed.—To make a useful hot-bed from stable-manure stone will require time, especially if the manure is peat. As it must undergo a regular process of fermentation for ten days or so before it is safe to put in a bed to raise seedlings, it will require at least two loads of manure to make a bed to raise seedlings, &c. When the manure arrives shake it all over, so as to separate it, and throw it into a conical-shaped heap. In three or four days it will be getting warm, and as soon as the steam begins to rise from it turn it over and

throw the outides of the heap into the middle, so that all may undergo the same purifying process. If there are any dry spots damp with water, or mix the damp manure from the outside of the heap with it. Probably this second turning and intermixing may be sufficient, but for safety's sake I have sometimes given the manure a third turn before making up the bed. In making the bed, first measure out the space as to have it 1 foot wider than the frame all round, and drive down a stake in each corner. The bed should be built in layers of about 1 foot thick, treading it down moderately firm after each layer has been placed on, until the requisite height has been reached. If the bed is likely to get very hot place a few barrowful of older manure on the top to be a check upon the fresher material below. The bed should be about 4 feet in height at the back, and from 3 feet to 3½ feet at the front. The fresher the manure the more pressure should be given. Build the sides up perpendicularly, or nearly so. When all is completed place on the frame, and place a thermometer in the bed, the bulb being sunk 6 inches in the manure, and as soon as the heat becomes steady at 90 degs. or a little higher put in 6 inches of Cocoa-nut-fibre or sawdust to plunge the pots in, and sow seeds, or put in cuttings.—E. H.

— If you refer to quite recent numbers of GARDENING you will find full information as how to make a hot-bed for seedlings. You must set to work at once, as the season is advancing.—C. T.

3126.—Repotting plants.—It is seldom wise to shake every particle of soil from about the roots of a plant, and even then when it is necessary to do so through its unsatisfactory behaviour. I presume you have fairly well-established examples, and if so, pot them on without disturbing the ball of soil more than necessary, just removing a little of the rougher particles. When the plants are entirely shaken out the roots are often much damaged, and thus progress is considerably impeded. Amateurs or beginners frequently come to grief over this matter. A reduction of the old ball of soil does not signify removal of every bit of soil.—C. T.

3132.—Worms in a Passion-flower pot.—I use lime-water and other things. The best course is to repot the plant, as you say the pot is crowded with worms. Turn it out carefully, and give an entirely fresh compost. I should think it is poor stuff that the plant is growing in, and be careful what soil you use; not leaf-soil, which is sometimes full of worms. The plant would do better planted out.—C. T.

3184.—Culture of Cyperus altifolius.—Sow the seeds in pots or pans of light soil now, or in batches any time when seeds can be obtained. I always save my own seeds from these and similar plants, and they come up as thick as Grass in the field. Place the pots or pans in the hot-bed till the seeds germinate, or they will do in the greenhouse. Prick off as soon as large enough to handle, either into boxes or pots. I generally start my plants in thumb-pots, and when they want more room shift into larger pots. There is nothing easier to grow.—E. H.

3104.—Eucharis eaten off.—It is not easy to say what has eaten off the roots. It may be the Eucharis-mite (Rhizoglyphus schinopus), but I could have advised better if specimens of the roots had been sent. A plan recommended by a correspondent in the Garden is to sink the roots in a mixture of 1½ lb. of soft-soap, and the extract from 1½ lb. of Quassia-chips to 25 gallons of water for three days, and then raising the temperature of the mixture to 115 degs. Fahr. for half an hour. It is proper to note that during the past three or four years the remedies suggested have been very numerous. The great point is to keep the plants in vigorous health, full of growth, and thoroughly robust. The same correspondent also advises the removal of all loose scales from the bulbs, and diseased parts cut out with a sharp knife, brushing them with the following mixture: Quarter of a pound of sulphide of potassium dissolved in three gallons of water, and then cook them in the same mixture heated to 120 degs. Fahr. for at least ten minutes. There are also advertised remedies, which will prove more or less efficacious.—C. T.

— Your Eucharis are no doubt suffering from the Eucharis-mite. There is no other known. The mites work their way into the roots where

no insecticides can touch them. The safest way is to burn the plants and the earth they grow in. The mites are very small, but may easily be distinguished with an ordinary pocket lens. They look like small rounded grains of sand with brown hind-legs.—G. S. S.

3116.—Propagating Echeveria retusa.—This is a charming Echeveria, bushy in habit, compact, and attractive when the plant is well grown. It adds beauty to many a plant-house in spring, and the wonder is one does not see more of it in gardens. Take off the side shoots, cutting just below where the wood has got rather hard, when the plants have finished blooming. They will soon strike if given some warmth, and a light soil used. Take care not to overwater the cuttings.—C. T.

3212.—Greenhouse fine.—I cannot see any objection to the proposed plan. If the new fine is longer than the old one make the chimney proportionately higher, and do not have more elbows as corners than can be helped.—B. C. R.

3107.—Culture of Chinese Primulas.—You may sow the seed in April, and if proper treatment is afterwards given the plants will bloom at the time required. By sowing at different times it is possible to maintain quite a succession. April, or even May, is early enough in the South of England, and March for the more northern districts. This is a general rule; but you may reckon about six months from the time of sowing until the plants bloom. A good way is to sow in late May for November flowering, and August for blooming in the following January. I saw last year excellent plants in October, full of flower, from seed sown the previous June. Sow the seeds in a shallow pan filled with a light compost, such as one composed of loam, one part, leaf-mould, thoroughly well decayed, two parts, mixed with sufficient sharp silver sand to make the whole porous. Cover the seed with a mere sprinkling of fine soil, and place the pan in a house or pit where a temperature of from 50 degs. to 60 degs. is maintained. After the seedlings appear prick them off into other pans, or boxes will do, using a compost similar to that commended above. Remove them to some house, but when commencing to make free growth remove them to cooler quarters, as a steaming heat is not necessary for their culture. When the seedlings are of sufficient size to handle pot them off separately into 3-inch pots, and at this potting a heavier soil is required, which is gained by adding more loam to the previous compost. A cold frame will suffice now, and during strong hursts of sunshine shade them. Always keep the plants near the glass to prevent the growth getting drawn. When the 3-inch pots become pot-bound shift them on into 5-inch ones, and a good compost is made up of turfy loam, three parts, and one-part of well-decayed manure and leaf-mould, with sufficient sharp silver sand to keep it open. Keep them close for a time after potting, but then ventilate freely, and when there is likelihood of frost remove them to the plant-house. Occasional supplies of weak liquid-manure will be beneficial at this stage. If you are a beginner I advise you to commence first with the single varieties.—C. T.

3180.—Bryophyllum calycinum.—There is no difficulty in getting this to grow; the only objection is that it is nothing to look at when you have grown it, as it then somewhat resembles the white-flowering "Winter" Begonia, only without the flowers. Any leaf of Bryophyllum, if struck edgewise near the rim of a flower-pot, filled with potting-soil and sparingly watered, will soon shoot out vigorously on one or both sides, just where the leaf enters the earth. The same trouble expended upon the White Begonia would give a far more satisfactory result; therefore, it is a pity to waste time and space on this tropical weed.—A. O. BUTLER.

3198.—Slugs in a greenhouse.—Turn two or three loads into your greenhouse, and they will soon reduce the number of your slugs for you.—A. O. BUTLER.

— Any application that might be applied to kill the slugs might also do injury to the Ferns. I should certainly catch them and kill them. Place slices of Carrots or Potatoes near the haunts of the slugs, and look over them two hours or so with a light after it is dark at night. Examine the Carrots every morning. In a week or ten days every slug might be captured.—J. D. E.

3128.—Alocasia zebrina.—This is a fine evergreen species from the Philippine Islands and requires an abundance of heat and moisture all through the season. You cannot dry this plant in the least without doing it an injury.—J. JAVIN.

3146.—The Ice-plant.—Mesembryanthemum crystallinum not so useful for carpeting, especially of Tuberos Begonia, as M. cordifolium variegatum, as there are few better subjects than this for the purpose. It all depends upon the size of the tubers. If large, from a foot to 18 inches apart would do, but less if small.—C. T.

3127.—Crassula lycopodioides.—This Crassula should be in flower now. Two blossoms are in the axils of the upper leaves generally in great profusion, but so minute that they are best seen with a magnifying-glass. Probably "W. C. L.'s" plant has flowered, but not been noticed on account of the size. Plants easily managed. Keep drier in winter.—O. D. B.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and seasons vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

3120.—Clematis Jackmanii.—Is it too late to cut down this plant? The shoots have already started to grow.—T. J.

3221.—Plantains on a lawn.—Will someone please tell me the best means for getting rid of Plantains on a Grass lawn?—SPAINA.

3222.—Hot-bed.—In making up a hot-bed, if leaves are not to be had, may straw be used instead for mixing with the manure?—E. L.

3223.—Tomatoes and Cucumbers.—Can Tomatoes and Cucumbers be grown in the same greenhouse, size 27 feet by 15 feet?—R. MASON.

3224.—Primulas for spring.—What sort of Primula seed should I buy, and when should it be sown to bloom early next spring?—R. MASON.

3225.—Grafting Rhododendrons.—Will someone kindly tell me how and when to graft Rhododendrons, and on what stocks they should be grafted?—A. B.

3226.—Auriculae and bottom-heat.—When should I sow this? I have a greenhouse and bottom-heat. If it is required. A few hints on their culture would oblige.—T. J.

3227.—Agaves.—I am desirous to form a collection of the best Agaves. Will someone please oblige me with the names and description of the very best varieties?—AGAVE.

3228.—Pruning Rose-trees.—Will someone kindly inform me if I should cut back Rose-trees to the third bud that were budded last year, or let them bloom first?—O. W.

3229.—Canna from seed.—Will someone kindly tell me if Canna-seeds sown now in heat will produce effective plants this year? How are they propagated?—FYMATH.

3230.—Canflower and Broccoli.—Will someone tell me if it is possible to have a succession of these the whole year; if so, what are the best sorts, and when to plant?—PRINCE.

3231.—Large-flowered Cereantheum.—Will someone kindly give me a list of about two dozen large-flowered varieties that do not grow higher than about 6 feet?—G. I. P.

3232.—Trapa bicornis.—I should be glad to know if the outer-burred shell of the bulb Trapa bicornis is part of the root, or whether it is moulded and the bulb put inside?—MRS. R.

3233.—Primulas for seed.—Will seeds of Primula blooming now be ripe in time to sow again this season? I suppose they do not require fertilising like Begonias, do they?—FYMATH.

324.—Pear "Louis Bonne de Jersey."—I wish to know if Louise Bonne de Jersey Pear is a good bearer and will do well in the north of Yorkshire? Will strong or light land suit it best?—BONO B.

3235.—Clematis corulea.—Is the Clematis corulea blue, as its name suggests, and to what use does it grow? Having a bed of it planted this year, do not know what to arrange to grow with it?—PAT-DE-GALLIS.

3236.—Carrotion cuttings.—I have had a number of Carrotion cuttings sent me from Riviera, and I should be glad to know if they are likely to bloom this year, provided the cuttings strike.—FYMATH.

3237.—Gasterias and Haworthias.—Will one of your correspondents kindly furnish me with the names and descriptions of the best varieties of the above, as I am desirous to form a collection.—GASTARIA.

3238.—Heliotrope on a wall.—I have a large plant of Heliotrope which I want to cover a wall in an unheated conservatory. Would it be best to fresh pot it? If so, what is the best soil for that purpose?—FRANK'S SONS.

3230.—Euphorbias.—I shall feel much obliged if one of your readers will furnish me with the names and descriptions of about twelve of the best Euphorbias suitable for growing with *Cacti* in a greenhouse?—E. THOMAS.

3240.—Clematis and Roses.—Will someone kindly tell me if it is practicable to grow *Roses* in a bed of *Clematis*? If so, the best kinds of each for affording a continuity of bloom throughout the season?—CLEM.

3211.—Paradise Apple-stocks, &c.—Will anyone kindly tell whether the *Paradise Apple-stocks* are raised from seed or cuttings, and where I could get them? Also if stocks on the *Crab* are raised the same way?—F. H. B.

3243.—*Shorthia galacifolia*, &c.—Will someone kindly tell me the soil and aspect most suitable for *Shorthia galacifolia* and *Heuchera sanguinea*, and are both really quite hardy? Locality, South Wales, near the sea.—W. H. J.

3243.—Cattle-fish and plants.—I have collected pieces of cattle-fish, washed up on the forebush, which, when dried, can be made into powder. Will anyone kindly inform me if cuttle is use for pot plants in a cold greenhouse and outdoor vine border? Is it equal to bio-dust?—SEAROA.

3244.—Making Asparagus bed.—I want to make an Asparagus bed. Which is the quickest method, and how long will it be before good crops can be expected, and which are the best sorts to put in, and what time? I also like to put in *Strawberries* to fruit this year well? Which are the best sorts for *Carmarthenshire*?—FAY-DE-GALL.

3245.—Classes of *Chrysanthemums*.—Would someone kindly tell me of what classes the following *Chrysanthemums* are, noting which are for summer flowering outside? I cannot find them in any catalogue I have. *L. Poets* do *Chrysanthemum*, *Mme. Dufoese*, *Mme. de Dubor*, *Mme. E. Lefort*, *Strathmeath*, *Lady Fitzmaurice*.—FIRA.

3246.—An *Asclepias* shedding its buds.—Should be glad of information as to the reason why an *Asclepias* sheds its buds—a ten-year-old plant that bloomed splendidly until three years ago, and although I have purchased proper soil from nurserymen, and started it in a greenhouse that keeps "Germanium" alive, &c., but not a flower?—FIRA.

3247.—Water Lilies from seed.—Are *Water Lilies* (White), easy to grow from seed; do they bloom same or following year; at what depth shall they be planted; and how and when? Which is the best season to put in plants, and be should they be managed? Must the water be run off for the purpose, and must the ground be prepared in any way?—FAY-DE-GALL.

3248.—Seeds of hardy perennials.—Which is the best plan for sowing seeds of hardy perennials, &c., or of 31-doz? Will certain kinds be more subject to rot and displacement by watering? I have a large variety to sow this year, many for moist and shady situations, and neutralizing, and am anxious for success. In the *Garden*, page 24, sandstone grit is recommended, but that I have not got.—FAY-DE-GALL.

3249.—Grubs and Ferns.—Would anyone kindly tell me what a white grub, with small brown head, something like an enlarged maggot let? On repeating my *Maidou-hair Ferns*, I found a dozen or more in several of the pots. I destroyed all I could see, and repeated, but there may be germs left in the crowns of the Ferns. Could I destroy these? And is there anything I could use with the potting-soil to kill possible existing grubs?—F. M. II.

3250.—Growing *Roses* in pots.—Would someone give a beginner a few hints as to the treatment required for growing *Roses* in pots in an unheated greenhouse? I have just received six *Roses* from the growers; they are all in 3-inch pots and are apparently quite young plants. My flowers are looked for this year? If they require pruning or manuring or much water? Must they be put out-of-doors in the summer, and, if so, are they to be turned out of their pots?—IGNORAMUS.

3251.—A town back-yard.—A few hints on the best means of improving a town back-yard with high wall will be appreciated. The main wall is available for cultivation facing the north, and is about 10 feet in height. I have tried till *Nasturtium* with very moderate success, probably on account of the absence of sunshine and hot bottom. What are the most likely plants or flowers to thrive, either climbers or otherwise? Would Ivy grow well without sun? If I made a rockery along the foot, would *White Rock* prove a satisfactory permanent grower?—H. B. R.

3252.—Growing Ferns.—Will someone kindly oblige me with a few details as to the management of a house devoted to the growth of Ferns? The house in question is about 8 feet square, glazed with rolled plate glass, carefully prepared. I will certainly be very particular in the details. *Davallia*, *Polystichum*, *Selaginella*, &c. Due provision has been made for heating, by which it is possible to maintain a temperature of 70 degs. Fahr., if necessary, and precaution is also taken to provide a damp atmosphere by means of troughs placed upon the heating pipes. Yet certainly something is wanted, as the new fronds on developing gradually become discoloured. In destroying snails and other vermin, of what strength may a decoction of *Quassia-chips* be used? For instance, what quantity should be boiled, say with one gallon of water?—A. LOVIN OF FRANK.

3253.—*Roses* under glass.—Would "F. U.," or anyone else, kindly advise me as to the treatment of the following *Roses* I have wanted out to the border of a cold house? *Kinds* are *Obsidian Hybrid* and *Gloire de Dijon*. The *Gloire* were taken from the open; the *Obsidian Hybrid* were bought in pots and turned out. All were planted last November. The shoots of the bushes are just long enough to be an inch or two above the staging. What I want to know is must I train the shoots straight up or bend them sideways, and try to get them to break at a strong eye? If I bend them sideways they will be below the level of the stage, and, of course, cannot get very much light, and, in consequence, might break very fresh. I would like to see now what you think the present wood will never amount to much.—KOW.

3254.—*Carnations* for market.—I am thinking of erecting a cheap house to grow *Bouvier* de la Malmaison *Carnations* for market. I have a practical knowledge as a private grower, but I want some good growers' advice how to produce them in quantities for market. What is the best shape and size of house for growing out blooms? What aspect? What heat required? Which is the best way and best time to start? Would it be best to buy the best plants in July and layer them, or purchase young stock now? What are the best sota pots to grow them in, and the periods of potting?—CARBATIO.

3255.—Forcing *Rhubarb* and *Seakale*.—I had twelve stools of each, and in November I prepared and got a lot of ashes and covered them about 1 inches deep, and I covered the *Rhubarb* with stable-manure, and mixed it with leaves. I cut three dozen December 22nd last, and it was exquisite in flavour and size. The *Rhubarb* I covered with 25-lb pots and covered it with stable-manure, and the first lot was December 15th, and it was 16 inches by 1 inch. I have taken off 300 dozen up to date. Could I obtain it sooner than the date mentioned? If so, any information will be thankfully received.—GARDENER.

3256.—Plants on the back wall of a viney.—I should be glad of a few hints as to the plants most suitable for covering the back wall of a lean-to viney, 30 feet by 12 feet, facing S.W. The roof has a sharp pitch, the eaves are 4 feet high. 4 to 5 vines (*Black Hamburg*) are three years old and 6 vines number, started naturally, and the house is quite cold in winter, but well heated in summer. There is a good border, 3 feet wide by 18 inches deep, beside back wall. I had thought of planting a *Marshall Niel Rose* at south end, and a *Lapageria* or *Faeson-flower* at north end, with a few strong *Fuchsias* between these. Would these be suitable, or will someone please suggest something better?—LUNNANFIELD.

3257.—Water plants.—I shall be glad to know names and culture of hardy plants for edge of water to make a show of colour and plants which will grow in shady places or under trees, as I have much eady grass in my garden and under high trees, where I about 12 pines (*Black Hamburg*) are in parts of my garden where at some time rubbish has been thrown, and which is now covered with *Grass* and *Nettles*—*Snowdrops* coming up in profusion at this time of year. The *Nettles* and other coarse-growing weeds are allowed to remain, as they make cover for the pheasants, but I think something might be done to improve so unightly a place, as it is near the house. I should be most grateful for assistance in these matters, wishing to beautify a garden as quickly as possible, which has hardly anything in it. Buying plants on a large scale is very expensive, though I have already put in a quantity of hardy herbaceous plants to get flowers this year.—FAY-DE-GALL, Carmarthenshire.

3258.—Growing *Chrysanthemums*.—I wish to grow the following *Chrysanthemums*, so that none shall be more than 6 feet 6 inches high. Which plants shall I cut down in May, and which varieties, if allowed to grow without cutting down, do not reach or exceed the given height? I only want three or four blooms to each plant. Will the blooms from out-down plants be so fit for show as those from plants not so treated, but allowed to grow without cutting down? Is there much difference in the size of the blooms from out-down plants and those not out-down? My varieties are: *Etoile de Lyon*, *Bartier Reudatter*, *Source d'Or*, *L'Adorable*, *Florence Porey*, *Edouard Audiguer*, *Staudes White*, *Sunflower*, *Charming*, *Mme. Bernard*, *M. de Jacon*, *Comte de Germain*, *Mme. Bernard*, *Jeanne Deleau*, *Bunet*, *Louis Bahmer*, *Avalanche*, *Vivand Rose*, *Lord Alcester*, *Empress India*, *W. H. Lincoln*, *Violet Rose*, *Mme. C. Audiguer*, *Belle Paris*, *Edwin Molyneux*, *Mrs. J. Wright*, *Lady Selborne*, *Mr. G. Orchard*, *Alpheus Hardy*.—ANTHORA.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3259.—*Odontoglossum Rosei majus* (J. R. Loxley).—Your plant coming into flower now is quite seasonable, and it will last in flower a long time if you do not give it liquid-manure. You, growing *Orchids* in a window, should by no means think of using liquid-manure.—M. B.

3260.—*Begonia*'s roots eaten (*Momera*).—The roots are badly infested with the grub of a weevil. These should be carefully destroyed, in order to prevent further mischief. The leaf-mould may have contained something that was infested with them previously, and have thus caused the mischief to become intensified. You should carefully search for these pests and kill them; that is the only way to get clear of them.—J. JARVIS.

3261.—*Adiantums* dying off.—H. C. asks if this is necessary. A friend has told her that it is so, and that all the fronds should be cut away at this time. No; you treat this advice with indifference. Many people do dry off the *A. onnestum*, and get a batch of new fronds every year; but to treat all the family sots a very great mistake. Yes, get them and cut away any old fronds or pieces; this is the best time to do so, when the young fronds are partly grown. You must name the kinds of *Adiantums* you have before I can offer you advice as to temperature.—J. JARVIS.

3262.—*Cypripedium obovatum* (H. C. Amateur).—This seems to be the species to which the leaf sent belongs, but it is not a very fine one to judge by. The plant comes from warm parts of Burmah, growing upon limestone rocks. To grow it well under cultivation is a feat which has never yet been accomplished; but when I have seen it doing best it has been potted in a mixture of light, turfy loam and leaf-mould, with the addition of some pieces of limestone in the soil, and with the drainage material entirely composed of the last named substance; give it plenty of heat and moisture, and let me know how you succeed.—M. B.

3263.—*Dendrobium Leochlanium*.—C. Harbrook is a fine specimen to me. I received this plant in a pot, and who got it from Burmah two years ago. What treatment does it require? Now, I do not think it

possible that your friend could have so received this plant, unless it had been taken out to that country in the first place, because it is a form which was raised by hybridization in this country some years ago, and not likely to occur there. It must be a plant that had got put amongst some that your friend had received from that land, or he has given you this one in, or something must have happened in a similar manner. It is not possible to impart this English garden hybrid.—M. B.

3264.—Ferns in bad condition.—H. T. says: "I have just taken to a place, in which there are two fornicies, but the inmates are in a wretched condition." To this I would say, now is just the time to take to it, and if you treat the plants properly you have a splendid opportunity to distinguish yourself by showing an improvement. You may get ready for repeating, and do it whenever you like. The sooner the better; but in doing this be sure you drain the pots well. Good drainage enables one to give water more freely, and without incurring any risk. This is just the time I should like to take to a place that had been neglected.—J. J.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruit sent to name should always accompany the parcel, which should be addressed to the EDITOR OF GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of Plants.—Sydney.—1, *Cypripedium barbatum*; 2, *O. villosum*; 3, *O. Boxall* (all very good varieties); 4, *Lycaste Mesosealium*. The *Ocology* bulb is not of much value, and we do not know how to advise you without seeing the plants.—C. Earl.—1, *Adiantum acuminatum*; 2, *Adiantum Hookerianum*.—B. F., Bristol.—1, *Adiantum acuminatum*; 2, *Look like an Escutcheonum*; 3, *Scoroppy*; 4, *Dendrobium*, cannot name; 5, *Dendrobium Falconeri*; 6, *Too scorpy*; 7, a form of No. 1, should like to see it again. —Onward.—1, *Nephrolepis pediculate*; 2, *Pteris aristata*; 3, *Pteris cretica albo-lineata*; 4, *Adiantum onnestum*; 5, *Asparagus plumosus*; 6, *Selaginella pubescens*; 7, *Adiantum macrophyllum*; *Pteris acrostichata cristata*.—Overture.—1, *Dicksonia fibrosa*; 2, *Cyathea dealbata*; 3, *Pteris argyrea*; 4, *Coprosma Hameriana variegata*; 5, *Selaginella dichotoma*; 6, *Selaginella pubescens*.—T. H.—1, *Acacia grandis*; 2, *Apparently A. divaricata*. Probably pruning would be the best plan.—A. V.—*Skimmia japonica*.

Catalogues received.—*Florist's Flowers*. Mr. John Forbes, Hawick, Scotland.—*General Catalogue*, Messrs. Ellwanger & Barry, Mount Hope Nurseries, Rochester, New York.—*Farm Seeds*, de. Messrs. Little & Ballantyne, Carlisle.—*Show and other Pelargoniums*, Messrs. J. R. Pearson & Sons, Chiswell Nurseries, Nottingham.—*Bone and Special Manures*, de. Messrs. Proctor & Rylands, Carr-lano, Birmingham.—*Farm Seeds*, Messrs. Little & Ballantyne, Carlisle.

BEEES.

SEASONABLE NOTES.

COLONIES being in possession of a fair supply of food usually begin to rear broods as early in the season as the latter part of January or early in February. A small patch of brood at first appears in the centre of the cluster of Bees, this patch is enlarged and small circles of brood appear on the next adjoining combs, and spread gradually as the season advances, according to the strength of the hive, until it fills the cells not occupied by honey and pollen. The chief point to be kept in view in order to make Bee-keeping a success is to have stocks always strong; this is accomplished by means of stimulative feeding and spreading the brood at the right time.

FEEDING.—The time for commencing feeding depends much upon the state of the weather, but on a fine mild day at the end of February or the beginning of March the hive should be examined in order to ascertain its condition in respect to stores on hand and what amount of brood rearing is going on. By uncapping some of the honey cells the Bees will thereby be stimulated to continue brood-raising with greater vigour. Should the hive be found short of stores at this examination Barley-sugar may be supplied, and syrup later on, for when the weather is cold and the Bees not flying, they will take Barley-sugar or candy in preference to syrup. Pea-flour is used largely in the rearing of the brood if supplied to the hive, either in the form of Pea-cake or by sprinkling it on shavings or anything of the kind, placed in a box, pan, or skep near the hive, from which the Bees will eagerly gather it on bright, warm days. Much water is used by the Bees in the spring in preparing food for the young grubs. A pan of water, having floats of Cork or small pieces of wood in it for the Bees to alight upon, placed near the hive will be of great service, and save much Bee life in rough, windy weather, as in the breeding season Bees will venture out long distances in search of water. By careful feeding and spreading of the brood the apianian is enabled to get the hive full of Bees to take full advantage of the honey harvest when it arrives. In those places where the main crop of honey is from fruit-blossoms, it is, of course, necessary to be earlier in stimulative

feeding than in those districts where White Clover, Limes, or Heather are the chief sources of supply.

BROOD-SPREADING.—Except in the hands of experienced Bee-keepers, brood-spreading is a somewhat risky operation, for should the nights prove cold when there is brood on the outside combs and there are not great numbers of Bees in the hive, those on the outside combs will crowd to the centre for warmth, leaving the brood uncovered, which will, in consequence, become chilled, trouble, loss, and failure being the result.

FOOD.—Syrup is made by dissolving white lump cane sugar in the proportion of 10 lb. to 7 pints of water, with the addition of 1 oz. of salt and 1 oz. of vinegar, and boiling for a few minutes. There are many kinds of feeders for supplying the syrup to the hive, one of the simplest being a wide-mouthed bottle, which after being filled with syrup is inserted over a vulcanite stopper, which is so perforated that the bottle covers one or more holes, allowing the bees to take the syrup slowly or quickly.

BIRDS.

3305.—Macaw pulling its feathers.—My Macaw is pulling out her feathers badly. She is suffering, I think, from Christmas excesses, but is generally fed plainly on grain and water.—SOSBER.

3304.—Treatment of a Parrot.—I should feel very grateful if "Doubting" or "A. G. Bntice" if they could give me advice on the following query: I have a very valuable Parrot, and since the 15th of this month she has hardly been able to put her right claw to the perch. On the 16th she had a bath. I suppose she hurt it in some way or other than, as it was all right before that. She is very tame, and I can do anything I choose with her. The claw is in no way swollen, but she turns it in under her wing as if in great pain. Should the nails be cut the same as a Canary? I might state the Parrot is quite well in every other respect, and seems just as talkative and cheerful as ever.

3303.—Sudden death of Canaries.—What is the probable cause of the sudden death of my Canaries? A male which was kept in a sitting-room was found dead the other day. His food was Canary and Rape-seed, but he a fortnight it had had about a dozen Hamp-seeds per day, partly because it had had a slight cold, and partly to teach it tricks. It had quite recovered from the cold apparently, flung in the window, and was removed at night to talio. Was allowed to fly about the room. No gas was burnt in the room. This is the second bird that has died in the same way.—W. GOSWICK.

3302.—Bullfinch losing its feathers.—I have a Bullfinch, whose head has been quite bare for about two months. It is kept in a large cage with other British Finches, two of which have lost some of the feathers from their necks, and do not appear to be growing any more. I give a mixture of Canary and Rape-seed, with a little Hemp, Millet, and Ings. I should be very much obliged if somebody would tell me what this is caused by and how to cure it.—BIRCHEN.

3299.—Java Sparrow.—Will anyone kindly tell me what to do for my Java Sparrow? His head is quite bald, but the rest of his feathers are all right.—BOS.

POULTRY & RABBITS.

3270.—A poultry-house.—Will someone kindly advise me as to the best description of poultry-house? I have 20 fowls, and keep chickens for the use of our own table (about 25). Of what dimensions should poultry-houses be, also the run? Are movable ones made of wood to be recommended? Must they not be cold and difficult to keep wholesome and clean?—A BRUNING.

3101.—Fowls losing their feathers.—The fowls are like many others which are kept in confinement, addicted to the habit of feather-eating. It is not possible to recommend a cure which shall prove effectual in all cases, but a simple one is to cut the edge of the upper beak of the fowl. This prevents it taking a firm hold of the feather, and so it gives up the habit in disgust. There is no difficulty in cutting the beak. All that is necessary is to use a sharp pocket-knife, and cut away the hard edge. Do not cut into the quick, and it is not necessary to cut the lower half of the beak. This does not interfere in the least with the fowl's eating, nor is it easy to distinguish at the first glance a fowl which has been thus treated. I mention this to show that a bird is not made unightly by the cutting as many may suppose, nor does it undergo any discomfort by the mutilation. I know of no other cure. I believe the habit to be taken up through lack of occupation; it may also arise through the non-supply of green food and water. Fowls at liberty rarely, if ever, take to the habit, and generally discontinue the practice on being liberated from a confined run.—DOULTING.

3140.—Insects in potting-soil.—The insects you find in your potting-soil are, I expect from your description, which, however, is a very meagre, one of the many species of Springtails (Tribus amblyopoda). This species, however, has no springing apparatus. You cannot do better than bake the soil, unless you could place it where the small birds could pick it over.—G. S. S.

HOOPER'S Grand Strain of PANSIES.—Awarded upward of 50 medals. Seed saved from 1,000 choice exhibition named varieties, 1s. and 2s. 6d. per packet, 10s. for each.—F. HOOPER, Fancy Grower, Bath.

SPECIAL CHEAP OFFER.—6 Geraniums, 6 Fuchsias, 6 Double Ivy Geraniums, 3 French Lavender, 3 Heliotropes, 2s. from.—A. TOMKIN, Florist, Balcup, Kent.

ROSES! ROSES! ROSES! 40,000 To select from, purchaser's selection, 5s. 6d. doz.; 6 for 3s.; 12 Chrysanthemum, show and other best vars., 2s. 6d. double Fuchsias, 2s. 6d. beautiful Malton hair Ferns, 2s. 100 Lovely freeds 2s. 6d., cart. post.—WREN & CO., Kenningham, Bristol.

POTATOES.—The Excel All, a new Scotch variety. Every grower should try them, as they will shortly become the leading Potato in the world, being the largest cropper, disease resisting, and capital quality. Cash with order. 50s. 3s.—Apply W. HARNARD, Bolton Perrier, Leeds.

FERNS, all hardy.—Oreopteris, Polystichum, virginia, rigid, Oak, Beech, amula, &c., 10, distinct, 1s. 6d.; 20 extra large varieties, 2s. 6d.; 50, 100, &c., correctly named, free.—J. HARRISON, Falside, Keady.

GERANIUMS.—Well-rooted autumn cuttings, carting paid by Parcel Post for cash with order. Scarlet Vesuvius, 1s. 3d. dozen; 7s. 100; Henry Jacoby, dark crimson, 2s. dozen; 12s. 100; John Tibbott, 2s. dozen; 12s. 100; Cygne, double white, and F. V. Raspi, double scarlet, 2s. dozen; Master Christine, pink, 1s. 6d. dozen; 10s. 100.—GIARIES FRENCH, Rutherfordbridge, Sussex.

TO BE SOLD.—A large quantity of Calceolae cristata, well grown, with numerous bloom spikes.—Trustees late J. STEVENSON, Timperley, Cheshire.

BEGONIAS.—A choice lot of double flowering tubers, second year's growth, from the best strain in England. Choice mixed colour, 2s. per 100; 15s. per 50; 4s. per dozen, post free.—JOHN FARMER, Florist, Stanhope-street, Hf. Lond.

CARNATIONS, 1 doz., 3s. 6d., including Penshurst, Raly, Reginald Hole, &c. Double Primroses, Harbottle Plant, cheap, 1s. 6d. free.—HOPKINS, West, Kentford.

DEVON & CORNWALL ROCKERY FERNS, including Omundus, 5s. 2s.; 100, 5s.; extra large, 100, 7s.; Omundus regina, 6s. 12s. 5s. 6d.; Primrose plants, 1s. 6d.; 100 2s. 6d.; extra large, 100, 4s.; all free.—BROWN, Brookdale, Kinserton, Devon.

MARGUERITES, yellow or white, Fuchsias, single and double, Deutzgera Chrysanthemum, 1s. 6d. doz.; 100, Primroses, 1s. 3d. 100; 5s. 500, delivered.—WILLIAMS, Fulking, Beeding, Sussex.

RARE BLUE EVER PEA, 2, 1s. 8d.; 12 royal, 1s. 6d. Crown Imperial, 6s. 2s. 3d. Clear Violet, 1s. 3d. Grand Auriculars, 2s. 6d.; Carnations, 3s. 6d.; Campanula, 2s. 6d. doz.; free.—MR. LANE, Biddenham, Belfast.

VEGETABLE PLANTS.—250 Tripoli Onions, 40 Lettuce, 20 Cabbage, 10 Radish, lot, free, 1s. 6d. 500 Tripoli Onion-plants free, 2s. 6d. Wallflower-plants, 100, free, 1s. 6d.—J. DUCKER, Haxby, Wavry.

LARGE PALM in Oak tub (Chamærops Portmanii), 7 ft. high, 8 feet 6 in. through, 3 Ferns in pots, 1 Blechnum Brasiliense, stem 10 inches, 1 Davallia, 5 ft. through, to be sold for want of room.—Apply GARDENER, Horstead Hall, Norwich.

I HAVE a splendid lot of CALCEOLARIA plants, 12, 1s. 3d., 10s. 31, 10s. 2s. Good stuff.—W. HARRISON, West Hadden, Rugby.

CARNATIONS, PICOTEES, and PINKS.

WE have pleasure in offering the following strong, well-rooted plants, securely packed, and forwarded by Parcel Post or rail free to any address on receipt of stamps or P.O.O. For doz.—n. d.

- CARNATIONS.—MRS. J. M. WELSH, pure white Glove ... 4 0 MRS. MILK, a grand flower ... 4 0 PURITY or GALLIBURY ... 5 0 TRUX OLD ORMOND GLOVE ... 3 6 MIXED BORDER, in a great variety of colours ... 4 0 Colour named varieties ... 7 6 MRS. REYNOLDS HOLY, terra-cotta ... 6 0

PICOTEES.—Choice named varieties ... 7 6

- PINKS.—MRS. J. M. WELSH, much superior to Mrs. Sinkins ... 4 0 MRS. PETTYFER, dark faced variety ... 3 8 ALICE BEE, white ... 3 8 ABOUT PINK, dark centre ... 3 6 MRS. SINKINS, pure white ... 3 0

STRAWBERRIES.—JNO. RUSKIN (new), strong, transplanted runners, per 100, 7s. 6d.

PYRETHRUMS.—DOUBLE, in named varieties, EXHIBITION, per doz., 1s.

EXHIBITION GLADIOLUS.

12 Choice named varieties, including AFRICAN, reddish-brown, white blotch, a great novelty; MARIÉ GIRISFINE, white, thimble rose, exquisite flowers; CONQUERANT, very brilliant carrying, white hand; LA VOX! PINK, yellow faced, four petals; GRAND L.I.L., delicate blue, distinct colour, &c., &c., post free for 6s. BELENDID MIXED, 2s. 6d. per dozen, 15s. per 100.

BRUNNING & CO., SEED MERCHANTS AND NURSERYMEN, 3, REGENT ST., ST. YARMOUTH.

DAHLIAS A SPECIALITY.

HUMPHRIES' First Prize varieties, which have been awarded First Prizes at all the large shows in England, including Crystal Palace, Newcastle, Brighton, Bath, &c. Grand pot roots for propagating, 4s. 6d., 6s. and 8s. per dozen. Show, Pomona, or Victoria, &c. Catalogue gratis.—HUMPHRIES, F.R.H.S., Nurserymen, Chippenham.

CHEAP AND STRONG PLANTS.

- 12 Begonias, tubers, mixed colour, single ... 2s. 6d 12 Begonias, tubers, to colour, extra large, for exhibition ... 2s. 6d. 12 Geraniums, superb named varieties ... 2s. 6d. 12 Geraniums, Vesuvius, scarlet ... 2s. 6d. 12 Geraniums, Jacoby's best crimson ... 1s. 6d. 12 Geraniums, white, 1s. 6d.; 12 Master Christine ... 1s. 6d. 12 Geraniums, solid red, 2s.; 12 Heliotropes ... 2s. 6d. 12 Geraniums, Golden Gem, 1s. 6d.; per 100 ... 1s. 6d. 12 Harrison's Musk ... 1s. 6d.

All carriage paid. HUMPHRIES, Nurserymen, CHIPPENHAM.

1,600 ACHIMENES Olven Away; 6 with every 1s. 3d. order; 12, in 6 named sorts; with every 2s. 6d. order for plants or seeds from this advert for one week.—TURNER, Lydiate, Liverpool.

CATALOGUES, as usual, free.—12 large packets of sunnits, 1s. 3d. and 2s. 6d. 12 large packets of perennials, 1s. 3d. and 2s. 6d. All sorts of Vegetable Seeds supplied in 1s. 6d. packets.

CUTTINGS, 6d. doz.—Auriculars, Roses, 1 ft. long, Flamborough, in large Viallets, 1s. 3d.; 1 extra large Auricular, 1s. 3d.; 12 large Cinerarias, 1s. 3d.

LARGE BOX FLOWERS, 1s. 3d. 2 H.P. Roses, 3s. Seedling Carnations, Fuchsias, Wallflowers, Tomatoes, 2s. 3d. free.—TURNER, Lydiate.

PENNY Fuchsias, Calceolarias, Musk, Geraniums, Marguerites, Primroses, Kalamathen, Calliopsis, 12 in 3d.; cuttings, 2s. 3d. free. Named.

SEEDS.—2d. packet; sample doz., 1s. 3d., free; larger, 3s. 6d. Godwin, Cyclamen, Primula, Cineraria, Begonia (single and double), Fuchsia sturtii, Geranium, Scarlet Tom Thumb, Colts, Heliotropes, Petunias, Musk, Tomatoes (red and yellow), Cucumbers (Prize Telegraph, &c.), Outdoor Cherkies, Astors, Brocks, Camas, Castles, Oils, Wallflowers, Lobelia, Emperor William, Blue, Daisies, Erythraea, Anemones, Mimulus, Tagetes, Phlox Drummond, Passion Flowers, Cissampelos, Farnum, Hollyhock, Balsams, Mignonis. All guaranteed new seeds.

EXHIBITION ACHIMENES in 10 named sorts, 12, 1s. 3d.; mixed, 1s. 3d. 3d. 3d. seed, The Countess, 2s. 6d. Named Chrys., 12, 1s. 3d.; unnamed, 2s. 3d., free.—TURNER, Lydiate, Liverpool.

CHRYSANTHEMUM SEED JAPANESE (American), 2s. 6d. pkt.; do. (English variety), 10s. Jap., Anem., &c., mixed, 2s. 6d. pkt. Begonia, Imperial giant-stem, 11 single 1s.; double, 1s. 6d. pkt. Primula, Imperial strain, 11 colour, single 1s.; double, 1s. 6d. pkt. Cyclamen, giant stem, mixed or separate colour, 1s. pkt. Tomatin Pandorosa, largest on earth, 2-3 1/2 lb. 6d. pkt. The Collinium, large packets, 10s.; half packets, 5s.—J. OWEN, F.R.H.S., Floral Nursery, Maidenhead.

CHRYSANTHEMUMS.—ROBERT OWEN, F.R.H.S., Floral Nursery, Maidenhead, Importer, Raiser, and Grower of New and Choice Chrysanthemums. The largest and best collection in Europe. Awarded 200 First-Order Certificates and 10 Medals. Illustrated, Descriptive, and Priced Catalogue free with Culture, 2s.

GERANIUMS, autumn-rooted cuttings.—Scarlet Vesuvius, 1s. 3d. doz.; 7s. 100. Mme. Thibaut (pink) and White Vesuvius, 1s. 6d. doz.; 8s. 100. Crystal Palace Gem, 1s. 6d. doz.; 10s. 100. Henry Jacoby (dark crimson), 1s. 6d. doz.; 10s. 100. West Brighton (pink), 1s. 6d. doz.; 10s. 100. Mrs. J. M. WELSH, Kenningham, Bristol.

grow to form the future "hush." When those have again extended 5 inches, top them a second time; afterwards allow them to grow uninterruptedly, not even deheading the blooms at all, but allowing all to develop. The list contains the names of a few others that are useful nowadays as large blooms, especially if exhibiting is thought of. These would also make good bushes, or they might be substituted for others more suitable for giving large blooms, of which there are plenty, and of dwarf growth too. Sources d'Or, Florence Percy, Edouard Audiguier, Ada Spelding, Sunset, and Lady Selborne, are those to be added to the list for "hushes." With the exception of Mrs. Falconer Jameson, none of the others give blooms from out down plants equal to those of the same kinds grown without cutting down or topping. Very good blooms are produced on out-down plants, most suitable for grouping, but where they lack is in the depth, which is much short of what it is in blooms produced from plants not interfered with at all, but allowed to grow away uninterruptedly. The varieties that will give large blooms and not exceed the height named, grown naturally, are L'Adorable, Val d'Andorré, Mrs. E. Jameson, M. Bernard, Lonie Boehmer, Avalanche, Viviani Morel, E. Molyneux, W. H. Lincoln, and Mrs. Alphonse Hardy. Of course, "Antelope" must understand that in giving the list of names said not to exceed the height mentioned, I am assuming that the plants have been growing and will continue so to grow under favorable conditions in a cool temperature with abundance of light and air, as so much depends upon this in determining the height of any variety. If the plants are huddled together in a warm house the growth is sure to be weakened and the height increased correspondingly. By omitting the remainder of names, "Antelope" will know which sorts require cutting down in May to ensure their being of the height required.—E. M.

3245.—Classes of Chrysanthemums.
—Lady Fitzmaurice is yellow in colour, and belongs to the reflexed section, very free flowering, and early out-of-doors. Strathmeath is an early-flowering Pompon, rosy-pink in colour, very distinct, and free. La Poite des Chrysanthemums, Japanese, colour, rose-violet and white. Mme. Dufosse is an October-flowering variety; colour, crimson-red, tipped golden-yellow, centre old gold. Mme. de Duber, also an early-flowering kind, having bread petals, creamy-white, striped rose, and of large size. Mme. E. Lefort, early-flowering Pompon, dark golden-yellow, shading to red in the centre, of capital quality. "Fife" will see that all are good for early-flowering outside.—E. M.
— La Poite des Chrysanthemums, Mme. Dufosse, Mme. de Duber, and Strathmeath are early-flowering Japanese varieties, the first three being of French origin, and the last from America. Mme. E. Lefort is an early-flowering Pompon (French). The season of blooming of all is about October. Lady Fitzmaurice is a reflexed variety.—B. C. B.

3251.—A town back garden.—You will not achieve much under such conditions. I should certainly try Ivy, as it is not averse to shade or moisture—in fact, grows best when thus placed. The variety Emerald Gem would prove an excellent kind, as it is very vigorous in growth, and makes rapid progress if good plants are put in, or you could select the ordinary Irish Ivy, the large-leaved Regeneriana, but don't attempt to grow the small variegated kinds. You might try also Vestch's Virginian Creeper, and at the base of the wall you could grow Ferns; but I should not make a rockery, as without sun, and enclosed in such a prison, practically nothing would grow except Ferns, as to get flowers sun and air are essential.—C. T.

I should recommend you to confine yourself to the large variegated and the small wood Ivies for the wall, and if you make a bed with rock work at the bottom plant it with Ferns and Stonecrop. It is of little use to expect flowers to bloom under such unfavourable conditions.—A. G. Evans.

MILD.—Leaf-mould.—The best leaves for making leaf-mould are, generally speaking, Beech, Ash, and Lime, also, though cut at ways to be had in plenty, Hazel and Briars. Sycamore and Oak are not generally so useful, as they are rather longer in decomposing, nor are Holly or Laurel.—PARRY.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be sent you in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

GARDEN WORK.

Conservatory.

There are plenty of cuttings now on Tree-Carnations, and if more stock is required, cuttings will root very readily soil on a stem-heat. I have seen them rooted very successfully in sand and water in flower-pot saucers placed on a flue or hot-water pipe, water being added as it evaporated, the cuttings potted up as soon as roots were formed without waiting for them to heal. The first batch of Obyrsanthemums will now be established in single pots, and will soon be ready for shifting into 5-inch pots. Where a few very fine flowers are required there will be no stopping, and therefore it is necessary that the plants be grown cool to keep them sturdy and dwarf, or, at least, not to run them up unmanageably tall. My plants are at present in a cool, light house, where the frost is only just kept out, and as room as it is safe to do so they will be moved into a cold frame, and ultimately be placed in an open situation in the open air. Cuttings may yet be taken for conservatory decoration and to supply out-bloom. Pot or prick off early-sown Oyclamans, and set a few of the best plants on one side to ripen seed. This is quite a necessary thing to do in the case of all florist flowers, such as Primulas, Cinerarias, Calceolarias, &c. Once set a good strain, and then begin a regular system of selection, and there will be no need to be dissatisfied. Hereafter to grow a lot of rubbish for the sake of the few good flowers which each packet may contain. The new large-flowered Canans are charming things for the conservatory and to move to the house. Seeds of Gray's new hybrids may be purchased at a reasonable price, and if soaked in warm water for 24 hours to soften the skins of the seeds they will quickly germinate to bottom-heat. When the seedlings go out of bloom, move the plants to a shade in a light, sunny position, and supply with water till the growth begins to ripen, and then gradually dry off and leave them to get the bulbs thoroughly ripened. Cuttings of Double Patinias rooted now will make nice blooming plants during the coming summer. I once rooted a packet of seed which contained some very beautiful varieties, and seedlings make good plants for growing on in pots the following season. Another packet was obtained from the same firm, but there was no comparison with the first lot. Give liquid manure to Pelargoniums, and also to specimen plants. To do Pelargoniums well they must have a light position, with a moderate, but free, circulation of air. Ivy-leaved Pelargoniums make very useful specimens for the conservatory; baskets filled with strong plants now will be a charming feature during summer and autumn.

Stove.

Cuttings of winter-flowering soft-wooded plants will now be ready for potting off. The usefulness of this class of plants depends entirely upon being struck early and grown on rapidly during the spring and early summer months, the necessary ripening to be given in cold pits in August and September. During the growing season all strong shoots should have the points nipped out, and the plants should be shifted into larger pots as more root-space is required. To make up large specimens of such things as Begonias, Jussieias, Eranthisms, &c., several plants may be placed in one pot, and the soil kept given see that a good stock of Benwardia is worth up; young shoots strike freely in brick bottom-heat. Purty, the new white, is a good thing for the bouquetist. Rearrange the plants frequently. As a rule, stove plants, at this season, are too much crowded, and a frequent change of position will be useful. Climbers will require frequent attention. Pergularia odoratissima is a very old thing, but it is worth growing in a good-sized house for the sake of the delightful perfume. Thin out and train or crowded growth everywhere. This is a good season to plant out in boxes, or otherwise, such plants as Euphorbia jasquiniflora, Polioctis pulcherrima, Gardenias, &c., to cover exposed bare walls to view, as there are plenty of suitable plants for furnishing bare spaces.

Unheated Greenhouse.

Canterbury Bells are very pretty ornaments in pots, and should be lifted and potted in autumn, and kept in cool-house all winter. Some of the Saxifrage, especially S. longifolia var. and S. pyramidalis, are as effective as most of the tender things grown. There there is the tuberous-rooted species, S. palmata fl.-pl., the white flowers of which are so charming in early spring. S. sermentosa also is a nice basket or vase-plant. Sedum carnea var. varietum is very useful for draping baskets, or a potting bench, and there along the stage is the striking effect; cuttings of them will strike freely now in heat. Very pretty too is the creeping Toed Flax (Lycaria cymbellaria) in a vase or basket, or to creep over rockwork, or to plant round the edges of tubs which contain Palms or other specimen plants.

Forcing-house.

Asalans, both Indian and others, are still helped on in heat to keep up a succession of flowering plants. Roses will do better now in a lower temperature. The best place to bring up Rosee now is a stove or deep pit, filled with leaves, in which the pots are plunged, or the blooms, when they are developed, are cut, and the plants, as they root, are kept at the other Roses are past the flowering season, pruned so much young wood so can be spared, and set up into suitable lengths for cuttings; in bottom-heat scarcely one cutting will fall. Wherever it is possible a bit of old wood at the base will be an advantage to the future plant.

Cold Pits

will be valuable now. No one has too much pit room at this or any other season. The possession of cold pits which can be sheltered by mats or other coverings will enable us to find room for all used-up plants for the sake of servatory to rear-cut; it will also give an outlet to thin out the plants in the fruit and other houses by a gradual removal of the hardiest subjects that will bear the lower temperature. As soon as the bulbs, &c., which have flowered are properly hardened they may be planted out, and their place in the pits taken by other plants on their way to the open air.

In cold or northern districts the operations referred to in "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

Window Gardening.

In the outside boxes shrubs will now be more or less bushy in foliage, and should be removed and the boxes filled with spring flowers from the borders; the plants, being lifted with balls, will scarcely feel any check. Primroses, Alpine Auriculas, Wallflowers, Daisies, &c., will be effective and form a pleasant change till the season comes round for planting in the temperature subject. Indorethers are plenty of bloomers, the most effective of which are bulbs, and among these Daffodils, single and double, are very conspicuous. These bulbs, after flowering, must be taken care of; the best thing to do is to plant them out in the border, and they may be lifted again on some future occasion. Dentula gradilis is a very pretty white-flowered shrub at this season, but it would not be in flower thus early without some help; but it forces easily. All plants in pots will require more water now.

Outdoor Garden.

Hardy plants that were brought in last autumn to small pots, and which have been plunged in frames, may soon go out. All small, delicate things will be better if placed in the reserve bed for a year or two to get strong. The value of a reserve bed consists chiefly in the keeping new or delicate plants in some place where an eye can be kept on them. Very frequently when small plants, which are generally small, are placed in the borders among old-established plants they have a habit of disappearing through being overgrown by plants of stronger habit. There are some hardy plants which are the better for annual transplanting. Most of the Perennial Sunflowers, Obyrsanthemum maximum, Pyrethrum uliginosum, and other strong-growing things which flower towards the end of summer and autumn, if transplanted annually, will be better plants yet to be pulled to pieces and transplanted; but the work must not be delayed any longer if a full bloom is required. Laced Pinks should be planted in autumn; but I have often repented border Pinks, including Mrs. Sinkins, later than this. The roots are lifted and pulled to pieces, and the pieces planted deep enough to cover all naked stems, and the soil pressed very firmly round them. All the Dianthus family do best in firm soil. Carnations and Pansies which have been wintered under glass, will be better plants to root in now, and in a suitable condition. Dress the beds with soot, and give the last forking over at once. Poplars, Sunflowers, and other hardy annuals may be sown.

Fruit Garden.

The change in the weather will tend to keep fruit blossoms back, and be to their advantage. Precocious buds very often suffer from frost. Pruning and training, even of Peaches, should now be finished, as the buds are showing colour. In pruning Peaches guard against overcrowding, and where the bottom branches show signs of wasting out, open the other branches, and the wood, when the bottom of the tree is well furnished. If there may be a furnished wall anywhere, have it in the centre of the tree, as there it can be speedily covered. No two shoots should be trained nearer than 6 inches; if this rule was always observed there would be no naked space on the walls, the trees would be healthier, and there would be less trouble with insects, and there would be finer fruit, and the crop would be more in bulk and weight if not in number. Frost-proofing under glass, and hold in readiness now. If it is decided to use heavy coverings, they should be taken off every fine day. I have seen good results attend the use of a double thickness of old fishing-nets, when stretched out upon poles, and I should not be disposed to adopt anything of a more elaborate nature; but a temporary coping, if the coping on the wall does not protect far enough to throw off the wet, is very desirable. This may take the shape of a 9-inch board and may be fixed under the coping on the wall and supported by brackets. There is a great saving of labour in the use of fishing-nets for covering blossoms of fruit-trees, when put on they need not be removed for some time. They break the force of the cold winds without altogether stopping the circulation. Stop the young shoots of Figs under glass at the fifth leaf, and then cut where crowded.

Vegetable Garden.

Take advantage of every opportunity for getting in the crops when the land and the weather are suitable. Better a few days delay than committing the ground to the latter without any preparation. Potatoes may be planted from this to the middle of April, or later in some districts; change of seed occasionally has a beneficial effect upon the crop. As a rule, it is useless to plant the American varieties on wet, cold land—in point of fact, Potatoes will not prove a paying crop upon such land, no matter what sorts are planted; still, some kinds will do better than others. Two of the best Potatoes for strong, heavy yield are, I think, Myatt's Prolific and Imperator. Plant Jerusalem Artichokes in rows 3 feet apart, and 18 inches apart in the rows. In rather heavy land I have had the best results from laying the sets in rather shallow drills and drawing the earth over them from each side, so as to form a ridge. Those who care to try the Chinese Artichoke (Stachys tuberosa) may plant now in rows 2 feet apart, and 1 foot between the sets; cover about 4 inches deep. The tubers are not expensive. Cover all the remaining Beekete crops with blanching material; for blanching, or if many of the sets are to be covered by covering with a new life. With few exceptions there is as yet plenty of time for sowing or planting in the open air; but in both these respects April is an unusually busy month, so that preparation should be pushed forward as

Work in the Town Garden.

By the month of March the sun has gained so much power that even in the heart of the smokiest cities vegetable, and particularly such as is protected by covering of glass, begins to palpably respond to its influence and to breathe a new life. With few exceptions there is as yet plenty of time for sowing or planting in the open air; but in both these respects April is an unusually busy month, so that preparation should be pushed forward as

rapidly as possible in the meantime. A few of the hardiest annuals, such as Cornflowers, annual *Oxyanthemums*, *Mignone*, &c., may be sown on a warm border; but the bulk had better be left until next month. Finish preparing the beds for *Cerations*, and get the plants set out as soon as the work can be performed properly. Borders or beds in which to plant out the perennials *Phloxes* (which succeed admirably in small towns and suburban districts, if not in the very noisiest places), *Pyrethrum* of the *P. roseum* variety, *Michaelmas Daisy*, *Oxyanthemum*, *Perennial Sunflowers*, and many other herbaceous subjects ought also to be prepared this month. Christmas roses, again, when increase is desired, should be divided and replanted in April, and for these also the beds should be got ready very shortly. Violets, unfortunately, never do much good in an even slightly smoky atmosphere, but where they succeed at all April is the right month to plant out the rooted runners of these also. Indoors this is a capital season for a general repotting in the greenhouse. Ferns of nearly all kinds are better repotted, or if necessary divided and replanted, when just starting into fresh growth than at any other time, and *Fuchsias*, "*Geraniums*," and indeed almost all other greenhouse subjects ought also to be partly shaken out and supplied with fresh soil and clean pots at about the present time. Finish potting off singly all the autumn struck "*Geraniums*" and others, and shift on a good batch of those now standing singly in 3-inch or 3½-inch pots into the 5-inch and 6-inch sizes for early summer blooming. Give *Carnations* to be grown in pots their last shift. The 6-inch size will grow a moderate sized plant well, but the strongest should have 7-inch pots, or two may be grown in the 8-inch, or three plants in the 9-inch size. Let a

away. These plants, having filled their allotted space, have to be shortened back every year after blooming. I usually prune in April, and then pick off all late blooms. Large plants bear a very large number of flowers—of course, many are thinned in the bud state. Several old plants of *Luculia gratissima* have also been pruned rather hard back. I find this the best way of treating them, as they soon break and grow very freely. The faded and dead blooms of *Arum Lilies* are removed and the stem twisted out as soon as the flowers fade or the flowers out. If these old flower stems are not removed the new flowers beneath are longer in coming. Made up another Mushroom-bed in house and took in a fresh batch of *Seakale* roots. Potted more roots of *Chicory* for forcing and placed in Mushroom-house. Mushroom-beds in being have been watered with liquid-manure, and in addition a tablespoonful of salt has been dissolved in each large pot (2 gallons) of water. Sowed seeds of *Stocks*, *Asters*, *Zinnias*, and *Phlox Drummond*. Not much heat will be given, as they will come stronger without it, and will be quite early enough for planting out in May. Sowing main crop of *Celery*, the sorts being *Major Clarke* (red), and *Sulham Prize* (pink). The last named grows to a large size and keeps well through the winter. Flaced protection over *Apple* and *Peach* trees on walls. I have used nothing for some time beyond a few *Yew* branches thrust in among the blossoms, covered with fishing-nets, kept from the wall by poles fixed in the ground 3 feet from the wall at the bottom and secured beneath the coping at the top. Where *Yew* branches are not employed a double thickness of netting is used. I should not presume to lay down any hard-and-fast lines for others to follow, but I know that a good deal of money has in some cases been

TREES AND SHRUBS.

BEST SHRUBS FOR FORCING.

DOUBLE-FLOWERED CHINESE PLUM.

A BEAUTIFUL shrub is the Chinese Plum, the common *Prunus sinensis*, though the double variety of it (flora-pleno, here figured) is the most ornamental and the most generally grown. It is an early-flowering shrub, of slender growth, the flowers being small and white, and in the double sorts are like small rosettes, wreathing every twig with white. It is now often, and should be far more grown as a pot-plant for greenhouses in early spring, but being perfectly hardy it may also be planted in the open shrubbery with excellent effect. B.

FORCING LILACS.

Few deciduous shrubs respond to the quickening influence of heat more readily than the Lilac, and few are more beautiful or more generally appreciated. A great deal of the Lilac one sees in Covent-garden-market comes from France, where a speciality is made of forcing it, and although it is called white Lilac, it is in reality the purple variety forced in strong heat, and kept dark, either by forcing in dark sheds or cellars, or else in glass pits heavily shaded. I need hardly say that this sort of forcing spoils the bushes, at least, for some time, and I think that the great majority of people would prefer it forced in a more natural manner, so as to get the foliage of a healthy green. The principal thing to be said in favour of such unnatural flowers as these is that they sell, and fetch a good price. The kind of Lilac that will be found most serviceable to ordinary cultivators is to have healthy young bushes, planted out on a sunny border, where the young wood will get well ripened. As soon as the leaves drop in autumn the bushes should be carefully lifted, getting up all the roots possible. Set them into pots and fill with finely-sifted soil; water freely to settle the soil, and cover the pots with dry leaves until Christmas, when they should be placed under glass in the warmest house at command. Syringe the tops every day until the leaves expand and the bunches of bloom are visible, then keep dry, but water freely at the root, and both foliage and flowers will be fully equal to that on outdoor bushes in June, and the plants will do good service for several years. J. C., *Hants*.

3220.—*Clematis Jackmani*.—It is not too late to cut down a plant of this variety; indeed, those of the *Jackmani* type are really herbaceous—i.e., they die down to the base each season. If you have this *Clematis* true to name the young growth you mention will be breaking from near the bottom, and the wood above it will be found to be dead. The *Clematises* of this type grow very strongly, and flower upon wood made during the current season. When the growth has reached full length a flower-bud forms at the point, more forming and breaking out laterally from under every leaf throughout the whole length of such shoots.—P. U.

—The *Clematis* may be cut back to where a strong shoot is coming away. If there is a good shoot near the base cut there and make that the leader.—E. H.

3225.—*Grafting Rhododendrons*.—In a private garden, the best way is to put up seedlings of the common *R. ponticum* in the autumn or winter. The stems should be not less than ½ inch in diameter. Graft them in March, and place them in a garden-frame over a hot-bed; but the heat should be well-nigh spent, as a steaming heat would injure the plants. The grafts should be put on much the same as *Apple* and *Pear*-trees are whip-grafted.—J. D. E.

—This is hardly the work for anyone to undertake who has to ask for advice how to do it. I may, however, tell you that the better forms of *Rhododendrons* are grafted on the common variety named *potium*. In many nurseries the grafts are put on these stocks in the spring, they are then planted in deep boxes and placed in a warm, close house, where they remain until the season is suited to the stock, and the former has made some growth. The boxes are then taken to a partially shady place in the open, and in the following spring they are planted out.—J. C. C.

Double-flowered Chinese Plum (*Prunus sinensis* f. pl.).

batch of the best shrubby *Calceolarias* also have flowering-pots at once; prepare the ground for such as are to be planted out, digging it deeply and manuring well. These plants never do so well, especially in a light dry soil, as when planted out some time in April. *Auratum* and other *Lilies* in pots should be brought to the light when the young growth appears, and the stems be gradually earthed up with rich loam in a rather rough state as they advance. E. C. H.

THE COMING WEEK'S WORK.

Extracts from a garden diary from March 11th to March 18th.

Tied down and stopped Vines in the second house and thinned the shoots where too numerous. It is a mistake to leave on too many shoots; have them at least 12 inches apart on each side, and they should be at regular distances apart. When the growth is crowded, the leaves must be small, and everything depends upon having good foliage. *Muscats* should be fertilized with *Hamburg* pollen, and it is sometimes necessary to gather this and save it for future use, as in our case the *Muscats* are not yet in bloom. Sub-solent is gathered for the *Muscats* house by holding a sheet of paper under each bunch of *Hamburgs* when the pollen is ready for dispersion, and giving the bunch a good shake by tapping the wire; the paper is then held under the next bunch, and so on. I don't know how long pollen will keep in condition, but a considerable quantity long enough at any rate to fertilize blossoms during the coming season if kept quite dry. *Large Camellias* in the conservatory, planted in border, are still full of blossoms and buds. At the same time the young growth is breaking

spent in providing covers for blossoms on walls &c., with no better result than has been obtained by the fishing-nets and feathery *Yew* branches. Planted more *Peas*, also sowed *Veitch's Cauliflower*, and *Self-protecting Autumn Broccoli*, *Brussels Sprouts*, *Curled Kala*, &c. Planted out *Lettuces* raised under glass. Sowed more *Radishes* on warm border. Planted another pot with *Dwarf French Beans*. Put in cuttings of a large number of soft-wooded bedding plants and others. Potted off cuttings and pricked off seedlings of various things. Stirred soil among flowering plants in beds and borders. Sowed seeds of *Dracopa lodivica* and *Cyperus alternifolius* in heat.

3232.—*Trapa bicornis*.—This is not a bulb in any way; it is a seed. How do you imagine it could be "moulded and the bulb put inside?" The "outer horned shell" you speak of is as much a natural part of the seed as the shell of a nut. Recently there has been a good deal of fraud practised with this peculiar seed or nut. I saw a whole barrow-load hawked on the King's-road at Brighton, and described as the Chinese Lily Bulb; also as a grand climber, producing magnificent blooms of blue, red, yellow, and pink colours. The vendor claimed that it grew 6 feet long in a glass of ordinary water, and that each bloom produced two more buds, all within six weeks! The flower is really a very insignificant affair, and white. P. U.

ROSES.

SEASONABLE NOTES.

OUTDOOR ROSES.—This is a very busy month among outdoor, as well as among indoor Roses. The manure I advised their being mulched with may now be turned in. Care must be used in this operation. Roses are often dug between too deeply, and many of their more fibrous and feeding roots get injured. Those of the Hybrid Perpetual, China, Benksian, and Bourbon classes should be pruned this month. The Teas and Noisettes will be better left until the early part of April. In pruning, use a sharp knife in preference to a secateur, and always cut back to a healthy eye, and if possible, one having an outward tendency. For the purpose of these notes, I propose dividing Roses into three classes, according to their strength or habit of growth. There are the extra vigorous growers, like Gloire de Dijon, Maréchal Niel, and Mdlla. G. Lutzet. These need the long growths of last year to have their points cut out only; while the wood that flowered, and also any weakly or lateral growths, may be cut away entirely. If these long shoots can be trained or pegged in a somewhat horizontal position, they will break into growth and bloom more uniformly. Next we will take the varieties described as strong growers, but not extra vigorous: General Jacqueminot, John Hopper, Madame Lambert, and Anna Olivier may be taken as examples. These need cutting back to within 6 inches or 9 inches of the shoulder all good growths break from. Here, also, the weak lateral wood may be removed entirely; so, too, may some of the centre wood, especially if they be rather thick. Lastly must come the weak or moderate growers; some of these are very beautiful: Lady Mary Fitzwilliam, Etienne Levet, Horace Vernet, Comtesse de Nadailac, and Souvenir d'Elise Vardon, may be given as examples of this latter class. Prune these by cutting away the very weak growth first; then shorten back the remainder halfway. There is no longer any need for protecting material, so that the prunings and this can be removed together, and the whole left tidy.

INDOOR ROSES.—March should see many blooms upon plants that were started about Christmas. Up to the present we have not had a particularly good time for Roses under glass. They need much more sun than we have been favoured with; even light days, without sunshine, have not been plentiful. Consequently, the foliage does not attain that healthy colour and stoutness of structure so much appreciated. A few hours of sunshine after so much dull weather will soon cause young growth to droop. This need cause no alarm. Sun, at this period of the year, is frequently accompanied by harsh winds, and upon no account should air be admitted if the least draught is likely to be created. There is no more prevalent cause of mildew, and this disease is so much easier kept at bay than battled with when once it has gained a footing. You may temper the atmosphere, and aid the drooping shoots very much by giving a sprinkle of clear, soft water, at a temperature of 70 degs. A little water scattered over the walks and walls will also assist them, and render the sudden increase of light beneficial instead of distressing. Increase their water supply, and afford them liquid manure about three times a fortnight. A little manure-water scattered about now and again will help them wonderfully. As a rule, amateurs do not bear in mind sufficiently the great benefits accruing from a little ammonia in the atmosphere. The syringing, so recommended last month, must still be carried on regularly: it keeps the foliage clean and healthy, and also guards against the attacks of insects in the most effectual manner. Young plants that were grafted as per instructions in these pages will now need a second shift on into 5-inch or 6-inch pots. This should be their final shift during the present season. Make a point of having them securely fastened to a neat little stick, taking the precaution of tying them to it around the part where graft and stock unite. By potting them a trifle deeper this time, the junction of stock and Rose may be entirely covered. There is great advantage in this, as the union is rendered more complete by both being able to grow more uniformly when buried in the moist soil. Besides this, they are more

apt to go off upon their own roots, and thus form an additional means of support, while any dormant eyes upon the graft will be much more likely to throw up in the form of stout and useful suckers. P. U.

3614.—Climbing Rosess in a conservatory in the Isle of Wight.—There is nothing unusual in the behaviour of that part of the Rose growths that are trained to the wall. As I recently stated in GARDENING, Roses do not do so well under glass when the growth is nailed to walls as when it is trained under the roof, and your case proves that I am right. It is pretty clear to me that the shoots on the wall do not get ripened, which is the cause of the buds not starting into growth regularly. With regard to the Maréchal Niel, there is just a suspicion that "canker" has set in on some part of the stem, probably just under the surface soil. From the information you send it is evident that the growth of the Roses was not sufficiently ripened for such early forcing. The temperature during the day was, I expect, too high at first, so there is none of the Roses you mention, except Fortune's Yellow, but what can be had in flower early if they are properly prepared for it. If you want Roses so early you had better grow them in pots, or else be content with them six weeks later.—J. C. C.

3250.—Growing Rosess in pots.—When a beginner asks for instructions as to how to grow Roses in pots in a greenhouse, and is so ignorant of the details of their culture as "Ignoramus" appears to be, it is necessary to give very minute details, for on these success or failure hinges. For instance, one grower might succeed and another fail simply by the choice of position. If the plants were crowded on a stage at a considerable distance from the glass, they would not get enough air and light to make healthy growth. They should be placed somewhere near the roof-glass, well exposed to light and air. They should be pruned now, by cutting them well back, and when they have started to grow repeat them. Use for potting soil three-parts of good loam, one of leaf-mould, and one of decayed manure with some coarse sand. The plants in 5-inch pots should be planted in flower-pots 7 inches in diameter. After repotting they will grow with greater vigour, and will certainly flower this year. Tea Roses are all the better for a little fibrous brown peat-soil mixed with the loam. If they are to be grown altogether as pot-Roses they must not be turned out of the pots at all, but after flowering should be placed in a sheltered position out-of-doors; but it is better not to turn them out before the middle of May. Tea-scented Roses are better to be kept under glass all the year round, but they must be kept in light airy houses, well ventilated. At all times keep the leaves free from green-fly and mildew. They do not require a very great supply of water.—J. D. E.

—The pots are rather small at present, but they are large enough if the plants have only recently been potted. If they are full of roots now they should be repotted very carefully into others two sizes larger. If they have long shoots you may reduce them one half in length, and the soil must be kept regularly moist. It is always best for inexperienced people to place their Roses growing in pots in the open air early in July. In no case should they be turned out of the pots, but they should be plunged to their rims in soil or coal-ashes.—J. C. C.

—It would have much simplified matters if you had given the names of the six Rosess. I could then have said what style of pruning they required. At present I do not know if they be climbers or not. Climbers should need no pruning at this time of year, being small plants just received from the grower. Other varieties may be pruned fairly hard, cutting back to a healthy-looking and prominent eye. You should certainly get blooms this season. As far as water goes, keep them uniformly moist throughout the whole ball of soil without making them saturated and sour. You ask a question which would need rather a long reply, so pray allow me to suggest that you watch the instructions given from time to time in GARDENING. At present I would not apply manure. You had much better wait until growth is active and give it then in a liquid state. Watch carefully

for insect pests, avoid draughts and sudden changes in the temperature, and for the next month do not hurry your plants in any way.—P. U.

3229.—Pruning Rose-trees.—I can only understand the query by supposing you mean that the stocks budded last year made a short maiden growth the same season. If such be the case, cut them back to the third or fourth eye. All stocks that were budded last year should be pruned back to the bud now. Take care to afford sufficient support to the young growths, to make sure that they get well connected with the stock, and steadied against wind and rain.—P. U.

—If your Rose-trees budded last year have made growth more than 6 inches long, they had better be cut back at once as you suggest, but if the shoots are only 2 inches or 3 inches long, and weak as well, they had better remain as they are.—J. C. C.

—Roses that were budded last year and made some growth should be cut hard back to within two or three buds at least.—E. H.

3253.—Rosess under glass.—You are quite correct in your surmise that the present wood upon your recently transplanted Roses will be of little service. I should prune them down rather hard, and endeavour to keep other plants from shading the young growths until they have advanced enough to over-top the existing you speak of; after which the growth would be getting sufficient light. It would only be the foregoing of the room that a few plants might occupy for a short time.—P. U.

3240.—Rosess and Clematis.—Yes, it is quite practicable to grow these two grand flowers together, and I do not know of a more satisfactory combination. The following is a good method to adopt. Use Clematises of the Jackmani type, and Roses that grow strong enough to be suitable for pegging down. You would not do much in trying to have both Clematis and Roses in full flower throughout the whole season, but they may be had in perfection alternately and with a few blooms of each between times. It is not too late to commence this season, but you would only succeed in getting the Clematis good during the coming summer. Plant strong growing Roses and Clematises alternately. I will suppose that your beds have been planted one season, so as to have the Roses established, and will not describe the routine of operations which I have found very simple and satisfactory. At the present time I shall prune my Roses, having already placed a good mulching of thoroughly rotten manure around them, pegging the Roses down in the usual manner, so often described in these pages. While the Roses are producing their main crop of flowers the Clematises are throwing up the long summer shoots that are a characteristic of the Jackmani type. These will commence blooming as soon as the Roses go off, and as they will have grown all among the Rose-wood that was pegged down, and which is now comparatively useless, a grand display of colour will follow upon that made by the Roses. In the meantime there will be many strong shoots growing from the base of your Rose plants, and this wood will be of service for flowering the following season. These two plants can be worked so nicely together. Late in the autumn, when both Rose and Clematis growth is dormant, the wood of the former, which has flowered, may be removed entirely. So, too, may that of the Clematises, neither being of any further service. The ground may be cleared, dug up, and manured. Both of them enjoy a rich soil, and the manure first applied may be dug in just previous to pruning and pegging down in the spring, afterwards adding another slight dressing. The class of Clematis I have recommended is very free flowering, and also dies down, more or less, to its base each season. As they produce suckers like growths annually, and these flower the best, it is very simple to grow these two grand subjects in one bed.—P. U.

3229.—Cannas from seeds.—If the seeds are soaked for twenty-four hours in warm water, and then sown in warm soil, and plunged in the hot-bed they will germinate quickly, and get large enough for planting out or potting on this season. If the seeds are sown without the warm-water treatment to soften the outer covering of the seeds, they will be a long time in germinating, and will not make very large plants, unless rushed in a strong heat.—E. H.

FERNS.

A BEAUTIFUL FERNERY.

This illustration appearing herewith represents a view in a fernery belonging to Mr. J. Halliwell, Lathrum House, Bury, Lancashire. On passing through the doorway of this fernery a scene presents itself which at once in imagination transfers the beholder to a lovely tropical district, such as is sometimes described by travellers who have seen Ferns revelling in their native homes. Entering the fernery, one looks upon a mass of sandstone rising tier above tier. From interstices and also from capacious pockets hang in graceful profusion lovely fronds of innumerable species and varieties of varied form and colour. The pathway winds in and out, gradually sinking lower and lower, while the rockwork rising on each side gives the appearance of the path having been hewn out of solid stone; here a mass projecting, there receding, and forming large receptacles in which the Ferns grow in wonderful health and vigour. Passing along this rocky foot-

number of young plants, others finely divided and cut; the noble Tree-Fern (*Alsophila excelsa*), *Microlepia platyphylla*, a rare species, but a splendid object; Gold and Silver Ferns, the lovely *Gymnogramma schizophylla gloriosa*, with its gracefully curved, finely-cut fronds, a picture of beauty; the Stag's-horn Ferns, the lace-like *Chellanthoe elegans*, with others of this genus; and *Pteris* without number. Every step that is taken brings to view species and varieties rare and beautiful, and seldom seen in private collections. One exceedingly beautiful Fern will be noticed in the illustration hanging gracefully over the rock—viz., *Adiantum concinnum*. This is indeed a lovely plant, such as is seldom seen. There is an absence here of the arches which so often appear in various fantastic designs in ferneries, and which very frequently spoil the effect, producing an unnatural appearance. In this fernery, while there is not the slightest trace of formality, the rockwork is so arranged that the Ferns and other plants growing at the bottom on the level of the footpath get an abundance of light. When the light is obscured by arches or the overhanging rocks

HARDY FERNS

The beautiful illustration (see p. 671, Vol. XIV.) of the Oak Fern ought to remove any doubts as to the value of hardy Ferns for decorative purposes; but, unfortunately, the term "hardy" seems to often imply a very inferior kind of plant, and hardy Ferns are no exception to the rule, and this feeling prevailed up to a very recent date, of giving to any hardy plant very scant attention, and lavishing all the good things on the tender kind. Happily a change has at last come over the scene, and now we find hardy subjects much enquired after; and not only is the hardy plant department better looked after than ever, but there are genuine hardy plant nurseries devoted solely to the culture of such things springing up in all directions. Hardy Ferns are especially valuable plants for supplying foliage for mixing with cut flowers, the various *Polypodiums* mentioned on page 671 being exceedingly handsome; then there are many evergreen hardy Ferns, such as the Black Splice-wort, that are far more lasting than Maiden-hair, and are also excellent as pot plants for decoration. Many of the hardy evergreen Ferns, when grown in pots and sheltered in cold frames, are invaluable during winter for decoration, when it would be unsafe to venture the tender kinds. Large masses of Hart's-tongue when well grown are especially effective; but because they are hardy plants they should not be fully exposed to gales of wind and severe frosts, or they will be useless for decoration, as it must be remembered that Ferns in their native glens get much more shelter than pot plants get out in the ordinary frame ground do, and in pots the roots are especially liable to suffer from frost. J. G. H.

View in a fernery.

path, at the extreme end a very attractive feature is a stream of water, which, after running along a rocky channel for a short distance, comes tumbling and dashing over the rocks obstructing its course. Three parts of the way down a miniature lake is formed, from which the water again escapes and falls into a deeper and larger receptacle, which, judging by appearance, the water might have made by its incessant fall and flow during past ages; going a little further, the stream disappears, like some mysterious underground river, to appear in a different place and be put to further use. Turning and looking towards the now invisible entrance, completely blocked from view by a large projecting Fern-clad rock, the prospect is very beautiful. One very striking thing is the perfectly natural appearance presented by the luxuriant growth of the various Ferns, Selaginellas, and other plants; *Adiantums*, large and small-leaved, growing in masses in the large pockets, and peeping out of crannies and crevices; *Davallias* creeping here and there over and up the rocks, showing their peculiar brown and white foot; *Aspleniums* in abundance, some large and spreading, bearing

injudiciously placed, the plants below them, which ought to be as healthy and in as good condition, or better than anywhere else, because more in view, are weak and drawn, and detract from instead of add to the appearance of the fernery. The requirements of plants in the matter of light should always be provided for, and in Mr. Halliwell's Fern paradise they show a healthy vigorous condition, as a result of this and other natural surroundings and provisions.

In addition to the Ferns there are many Selaginellas planted, some upright in growth, others forming tiny carpets of green, golden, or silver verdure. *S. caesia arborea*, with its rambling stems and branches and beautiful metallic blue foliage, might be in some tropical forest, it is so thoroughly at home. *Ficus repens* and *F. minima* creep up the stones, hang over the rocks, and spread in all directions. *Tradescantias* and a few other suitable plants give additional variety in form and colour, and altogether serve to make up a scene of beauty.

This fernery was constructed and planted by Messrs. J. C. C. and J. Birkenhead, of the Fern Nursery, Sale.

3249.—Grubs and Ferns.—It is utterly impossible for anybody to name a grub from so vague a description as "white with a small brown head;" it might be the larva of a beetle or a moth. If you have destroyed all you could find there are probably no more to be found, for caterpillars and maggots are not developed from germs, but from eggs; all the eggs producing your grubs were probably deposited at one sitting and hatched almost simultaneously. —A. G. BUTLER.

3252.—Growing Ferns.—I am inclined to think that your present trouble is imaginary. I can see nothing in the description of the house which you send to account for the discoloration of the fronds; and without seeing the plants I should say the discoloration is nothing more than what is natural to them, as the young fronds of many of the *Adiantums* and *Davallias* wear a bronzy colour when they first appear, assuming a greener shade as they get older. —J. C. C.

—The great thing is to maintain a constantly moist and sweet atmosphere and moderately warm temperature; 60 degs. to 70 degs. is a good range for most of the descriptions of Ferns mentioned. The browning of the young fronds may arise from an overdry atmosphere, but too much steam direct from the troughs on very hot water-pipes would also cause it by scalding. Put a good handful of the Brussels-chips into a gallon of water. —H. C. B.

3209.—Barbed wire fence.—No; you cannot compel your neighbour to remove his fence. If you cannot make some agreement with him the only thing you can do is to claim damages against him, in the event of your suffering damage. Your neighbour has every right to put up any fence he wishes, but if damages are caused thereby you can make him change it. However, I doubt your being able to claim any damages, as you have no animals to get lacerated in a market garden; in a field it would be different. I'm afraid you must "grin and bear it." —PADDY.

3201.—Boards by the side of beds.—These always have an artificial appearance, unless some edging can be planted which will in time hide the wood. I have tried various preparations to preserve wood in the ground; it always decays sooner where the wood is in contact with the surface. The best I have used is a mixture of pitch and tar in equal portions. Apply it boiling hot. Two coats are necessary; the first soaks into the wood, and the next applied, not very hot, forms a coat of glaze on the surface. —J. D. E.

—Original from a good dressing of tar would do, and I have always found the boards last as long with this material as with any other. —F. ILLINOIS AT

ORCHIDS.

DENDROBIUM FINDLAYANUM.

This is a fine plant, and one that seeds freely, I should imagine, in its native home, and it must be acknowledged to be the parent of some of the prettiest hybrids which have originated in our gardens at home. However, the flowers lack the odour of *Too Roses*, which is the prevailing characteristic in those which have originated from *D. heterocarpum*, another plant which would appear to seed freely at home as well as *D. Findlayanum*, which I infer it does from the great number of variations in the flowers of both species. Especially is this the case with the one now under consideration. This *Dendrobie* comes from the mountains between Burmah and Siam, but within the first-named country, and is another of the many species of the *Dendrobium* family which the land of Burmah has contributed for the decoration of our plant-houses. It is now about thirty-six years ago since this plant was first discovered, and about ten years later its flowers were first seen in a fresh state in this country. The many beautiful forms of it which have been seen since cause it to take a first place amongst the many fine species which bloom with us during the early spring months. It is a very distinct and well-marked plant in its habit of growth, the stems being much swollen at the joints, producing a singular appearance, and the somewhat ample leaves remain on the stems with the flowers, but they fall away afterwards. The blossoms are freely produced, mostly in pairs, and measure each some 3 inches across; the sepals and petals are white, tipped with rosy-purple. In some forms, however, the ground colour is of a light rosy-lilac, the large lip being yellow at the base. Outside this is a complete zone of white, and the lip is rosy-purple, the same as the ends of the sepals and petals. These remain a very long time in full beauty. This plant requires an abundance of light, air, and moisture, and thrives best when suspended from the roof in an open *hook-wood* basket. The East Indian house is the best place for it. The basket must be well drained, using for this purpose lumps of charcoal, because they are so much lighter than potsherds, and it may be understood that, in speaking of the drainage of hanging-baskets, I always mean this material. To avoid the asperity strain upon the roof, for soil, use the fibre of good brown peat and chopped *Sphagnum Moss* in about equal parts. During the growing season give an abundant supply of water, both to its roots and overhead from the syringe; but after growth is finished, it may be kept somewhat dry and cool. Treated thus, *Dendrobium Findlayanum* will be a great joy for the grower.

MATT. BRAMBLE.

ONCIDIUM PHALENOPSIS.

This is a lovely Orchid, flowers of which I sent me by "John Marshall," who says: "This epike is from a plant sold a few years ago as *O. oucullatum*, but its colour is as very different." Yes, that may be so, but still colour is not a thing that one can make any specific distinction from; but here I do see a distinction. Although many class this as a variety of *O. oucullatum*, I must incline to the side of Prof. Reichenbach, who made a distinct species of it, for I observe that the narrow part of the lip is very different in the true *O. Phalenopsis*, and the shape of the front lobe is also very different to that of *O. oucullatum*. Moreover, I am inclined to think that the majority of the plants in English collections bearing the name of *O. Phalenopsis* are really and truly the *O. nubigenum* of Lindley, which I also consider to be a distinct species; but the flowers sent by "J. M." are the true form of *O. Phalenopsis* introduced by M. Linden, of Brussels, about twenty-five years ago, and it is at once a marvellous beauty, and one that grows well in a very cool temperature. What elevation this particular plant comes from I cannot say, but the typical plant does not appear to grow lower than about 8,000 feet altitude, thriving up to 11,000 feet or even more. When at the extremes it becomes quite alpine in its habit and appearance. The spike of bloom of this plant bears some five to seven flowers, more frequently less; the sepals and petals which are nearly equal in size have a ground colour of creamy white

transversely marked with somewhat spotted bars with rich purple or crimson; the lip is large, two-lobed in front, white, the base spotted with numerous large dots of purplish-crimson, and a crest of rich yellow. The flowers last so long in perfection that they are very apt to weaken the plant if they are not removed. These plants I like best to grow upon a block of wood, putting a very small piece of *Sphagnum Moss* with them, because as the plants of this species grow naturally on trees and rock, they have nothing to encumber or lie about their roots. I prefer these plants to be kept in the *Odontoglossum-house*, although some growers do go in for greater warmth, and put them at the cool end of the *Cattleya-house*; but though they may do well for a year or two they soon die off. The plants should have exposure to the light, but carefully preserved from the sunshine, and in addition they like to be always moist, no drying season being necessary for them.

MATT. BRAMBLE.

SACCOLABIUM GIGANTEUM.

THIS is a beautiful species which I am asked to write a few words about by "Hugh McLaren." I am glad at any time to hear any one of my readers asking for some hints as to the cultivation of these much neglected warm-house plants, which were quite upset, upon home growers waking up to the knowledge that *Odontoglossum*, and other things from South America and Mexico, could be grown at home without the application of fire-heat for at least six months in a year. People then went fairly mad, got rid of their collections of East Indian Orchids, and went in for cool-house plants from the Western Hemisphere, quite ignoring the fact that there are plenty of plants in the East that no mountain residents, and that an elevation of several thousand feet in the East has as much an effect in reducing the temperature as it has in the West, and that there are many temperate plants natives of the East Indies, and these can be grown cheek by jowl with the Western ones; but the present plant is a warm-house one. I first saw the plant in flower at Furham Castle some thirty years ago, and since then I have seen many fine specimens in the various collections through the three kingdoms, Mr. Turner's, at Fendlebury, being one, Dr. Ainsworth's, at Lower Broughton, Mr. Turner, of Leicester, Mr. Dawson, of Meadow Bank, and Mr. Day, of Tottenham, all being conspicuous for the very fine specimens of this and many other species of the genus *Saccolabium*. *S. giganteum* is a plant that usually flowers in the autumn and through the winter months, and last week only I had a fine truss which was brought in by a friend, its delicious fragrance pervading the whole room. It is an erect growing plant, but never attains much height under cultivation, or perhaps we have never kept it growing long enough to prove what it would be. Its leaves are broadly strap-shaped, sheathing at the base, thick and fleshy in texture, about 1 foot long, and rich-green in colour, having streaks of lighter green running from base to the point. The spike varies from 9 inches to a foot or more in length, the flowers being thickly set, small but numerous, waxy-white, much spotted with violet-mauve, the lip being rich-purple, and terminating in a short spur, and being deliciously fragrant. A pure-white form I have before me now at the present time, which, although very beautiful, is not so fascinating to the amateur as the typical plant, whilst we have in the variety *Illustrate*, discovered by Mr. Linden, a plant more richly coloured than the typical plant. This species thrives best in a hanging-basket in the East Indian-house, where the thermometer never falls below 60 degs. or 65 degs. The basket should be well drained, and for soil use living *Sphagnum Moss* entirely. Give the plants full exposure to light, and shade from the burning rays of the sun, keeping them well supplied with moisture in the air and water to the roots.

MATT. BRAMBLE.

3222.—Hot bed.—Long litter which has been used for bedding will do for mixing with short manure, but dry straw which has not been used is not of much value for hot-bed making. Manure just as it comes from the stable, where straw has been used for litter, is best, and if quite fresh it must be fermented before

being used to make a hot-bed. The proper treatment has often been given in *GARDENING* and consists in chinking it to pieces and throwing it up in a heap, leaving it for a few days to get warm; then turn it over and intermix by throwing the outsides of the hoop into the centre and bringing the manure from the centre to the outside, thus exposing all to the purifying influence of heat. This turning and intermixing may have to be repeated if the manure is very fresh. When loaves can be obtained to mix with the manure, once turning will be sufficient, but there is no substitute for leaves that will carry on a lasting heat; but stable-manure, properly fermented, will do very well, and many people have nothing else to make the hot-beds with.—E. H.

HOUSE & WINDOW GARDENING.

TUBEROUS BEGONIAS FOR A WINDOW.

THE time is now at hand that these charming plants may be started, and as they are excellent window-plants, no time should be lost in procuring the tubers. For window work it is very desirable to have plants of a neat, dwarf habit—i.e., such as do not grow tall and lanky, but bring plenty of blossoms on short, rounded stems. The more ordinary kinds of *Tuberous Begonias* grow nearly 18 inches in height before the blooms appear, while the best varieties are a mass of bloom before they are a foot high. Tastes differ as to whether double or single-flowered *Begonias* are most to be admired; a few of each kind may be chosen from the lists of a good *Begonia* grower, and also a few of the semi-double varieties, which are specially adapted for window-boxes or hanging-baskets. Having selected the tubers, they should be potted in thumb-pots, allowing half of the tuber to appear above the soil, which must be light and sandy. The only danger the tubers are in at this stage, if kept free from frost, is from damp, and they should not be constantly watered, the soil being only kept just moist, but not wet. Before long small sprouts, not unlike those which are seen on Potatoes, will appear, and when these have grown sufficiently to have roots, the tubers may be given their first shift into the next sized pots, with slightly richer compost. A bag of special *Begonia* compost can be obtained by post with the tubers, which saves the amateur much trouble and difficulty; but in the earlier stages spongy soil or sand should be added to the compost, which may be given stronger at each potting. A sunny window, where draughts are not allowed, will grow *Begonias* well, if they are never allowed to become pot-bound and given a shift before the pot is full of roots, with plenty of water daily, though not in a saucer. In some cases they give trouble by dropping their heads just before they open; this is usually to be traced to some sudden draught of cold air—perhaps given in the morning when the room is swept—or to the fact that they have been allowed to become too dry, and then have been soaked with water. Care in these little matters will be well rewarded, and *Begonias* will accommodate themselves to more positions if well treated. They should be carefully hardened to the open air if intended for borders, window-boxes, or balcony work, and may be placed out-of-doors entirely after the end of May, when they will become very strong and vigorous. They prefer slight shade, however, after this date to a very hot situation, and need a good mulch of *Coccoa-nut-fibre* or *Moss* to protect the surface-roots, on which their well-doing largely depends, if placed in the full summer sunshine. I. L. R.

3207.—Manure for *Begonias*.—You need not indulge in fertilisers in the case of the ordinary bedding *Begonias*. The great point is to get the soil well worked, and, if heavy, made light by incorporating with it a fair proportion of leaf-soil, or old *Mushroom-bed* manure, if you cannot readily get the leaf-mould. It is a good plan to cover the surface of the base with *Coccoa-nut-fibre* refuse, and during the summer keep the soil moderately moist. *Begonias* like moisture. A soil in which there is some amount of peat is very beneficial. As you appear from your signature to be quite a beginner in the culture of the *Begonia*, look through recent numbers of *GARDENING*; several notes have appeared upon the subject.—C. T.

WHITE BELL-FLOWERS (CAMPANULA).

BELL-FLOWERS of all kinds and colours are always most welcome in the garden, and the white ones especially so, being valuable for cutting or growing in pots. Of late years the White Bell-flowers have become very and deservedly popular as market plants, the single flowers being "mounted" and used in many ways in bouquets, sprays, and button-holes, &c. The accompanying illustration shows a good type of White Bell-flower.

3247.—Water Lilies from seed.—These are not difficult to raise from seed, but in their young state they need care and much attention. It is quite possible to flower them the same year if the plants are raised early. I have flowered the charming little Siberian species, *N. pygmaea*, within six months of its germination. I should say sow them as soon as you can get them. Treat them as regards preparation of soil and sowing as you would ordinary seed, but afterwards immerse the pot in some receptacle that holds water, having just sufficient to cover the top of the pot to the depth of about 1 inch. If the seed is gathered and sown in late autumn the young plants will not appear till early the following year. It can be kept, however, if convenient, and sown in spring, as I believe it retains its vitality for a considerable time. At any rate, I had a very successful lot of young plants that were raised from seed gathered in Africa, and it was some months old before it was given to me. After the young plants have made two or three leaves they should be potted off singly in small pots and again immersed, slightly increasing the depth of water, and continuing to do so as they grow in vigour. As regards planting them—I assume the quietest means in the open, in pond or lake—there is no season better than the month of May, as then the plants have the year before them, and if they are fairly strong they will soon make progress and flower. In the latter part of the month of May, 1891, I planted nearly forty plants of all the best kinds. I did not expect to see many flowers that year, but the first opened on July 4th, and every kind produced some before that month was out, and they continued on till late in autumn; also ripening seed which was sown when gathered, and germinated the following spring. As to how planting must be managed one has to be guided by the conditions. If the pond was a natural one, and had a rich deposit of mud, the plants might be planted in open wicker baskets and sunk where they were required to grow. Old baskets would do, as they would more readily permit of the roots finding their way through and rooting into the mud. On the other hand, if the pond has no natural deposit, and it is so arranged that the water can be drained off, it should be done, and then a mound of soil could be made for each plant. In my case the pond was an artificial one, made first with asphalt, and then, owing to leakage, puddled with clay, whilst, worse still, the clay was full of Sedges and Typha, two weeds that Water Lilies can hardly hold their own against, and the problem was how to give the Lilies good soil, yet isolate them from devouring weeds. We overcame the difficulty by making for each plant a concrete box 4 feet square and 18 inches deep. It was a great expense, but the necessities of the case demanded it. I hope "Pay de Galie" will have no such great difficulty. In conclusion, I might add that Water Lilies are now most delightful and varied, some of the newer varieties having flowers 5 inches to 7 inches across, and of most lovely tints in white, flesh, pink, and yellow. I am sure many readers of GARDENING would like to grow them, and as doubtless many have the means, whilst the best planting season will soon be here, I will shortly contribute an article upon them describing the best. I should add for that about a foot of water stood over the crown of the plants. Summer's evaporation reduced it once to less than half that amount,

but the plants kept flowering, and I believe it is a fact that some of the newer hybrids do not require nearly such a depth of water as some of the old species.—A. H.

—They can be grown from seed, and if the seed could be sown early in the year the plants produced therefrom would flower the same season. It is not usual to raise them from seed. They are planted from divided clumps. Plant them now just before they begin to grow. The way I do is to fill a large round basket with loam and decayed manure. Plant in this, and sink the basket in the water, the crowns of the plants should be a foot under the water. If the water is run off they may be planted in the soil at the same depth.—J. D. E.

3109.—A rare Grass.—The Grass, *Pennisetum arenaria*, is not rare, as it is distributed on European shores, even to North Africa, growing in the dunes and sand-hills by the sea. The flowers are produced in July, and the root-stock is creeping, like Couch, thus binding the sand, for which purpose it is planted. In Carpenter's "Vegetable Physiology," it is mentioned this creeping atom, so troublesome to the Couch Grass, is of great service to man in the Grass called the Sand Reed, *Pennisetum arenaria* (bot, I

OUR READERS' ILLUSTRATIONS: A White Bell-flower (Campanula). Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. R. A. Bradley, Alderley Edge, Cheshire.

may remark, that it is also known as Warren Grass), which can vegetate amidst dry and drifting sand, and hence is employed to give firmness to embankments. Such Grasses do not increase so much by seeds as by the multiplication of buds; cattle will not eat them, and hence they are providentially adapted to escape that mode of destruction, but when they have been uprooted through thoughtlessness or ignorance the most serious evils have arisen. It is interesting to note that large tracts of nice fertile country have been rendered barren by the encroachment of sand hills, and this encroachment resulted from the destruction of such mat Grasses as the Sand Reed, which were pulled up by the country people for fuel to such an extent that an Act of Parliament was passed about 100 years ago, rendering it punishable to do so.—C. T.

3227.—Agaves.—The so-called American Aloe (*Agave americana*), is one of the best, and also the variegated variety, especially when small. I saw lately a quantity of it in a nursery, the plants in smallish pots, and noticed their usefulness and brightness. Both are excellent to adorn the garden terraces especially, and for this purpose are grown in large pots in which they may be plunged in the ground. They may be taken in during the winter and

used for the conservatory. There is also a variety called medio-picta, which is distinct from *A. variegata*, the centre of the leaf being of a golden yellow colour, and the margin green. *A. celaniana*, *A. pilifera*, *A. Shawii*, and one called *A. Victoris Regina* may be also recommended. The last mentioned is very distinct and compact, the leaves striped with white. It is by no means uninteresting or devoid of colour.—C. T.

3163.—Carnations bursting.—The trouble you speak of arises, unfortunately, not from the weather, but is characteristic of the varieties. They are what is known as "pod hursters." Bot Cermania, as far as I have seen and grown it, is not so bad as the others. Exhibitors have a little india-rubber ring to place round the calyx of those flowers that are likely to burst, or a piece of thin bass answers the same purpose. It is usually in the wet seasons that the flowers burst badly. Raisers of Carnations are ever striving to get varieties that keep the flowers intact, not bursting at all. A good garden Carnation should not split its flowers, but hold them well up on sturdy stems. There is no reason why the plants should not bloom well in the coming season, but on no account overdose with liquid-manure. It is not needful. Beautiful beds of Carnations I have seen without any of this kind of treatment.—C. T.

3254.—Carnations for market.—These are largely grown by a friend of mine, whose work and results I have many opportunities of seeing. His plants are grown in a house with a three-quarter span, and many of his plants are so large that it takes two men to carry them from the house to the open air. The best plan will be to buy plants at once, and as they do better in large pots than small ones, I would put three in a 10-inch pot, and pick off all the flower buds this year. The plants should be grown in the open air until the end of September, when they should be taken to the greenhouse for the winter. My friend takes his plants from the house about the middle of July and stands them on a gravel walk exposed to all the sun, where they only get just water enough to keep them alive. Any repotting is done when they are taken under glass in the autumn. A temperature of 50 degs. by fire-heat is as much as they can bear up to the middle of March, and then they must have plenty of air in suitable weather. During the months of April and May the house is closed early of an afternoon when the sun is bright, the thermometer often running up to 85 degs.—J. C. C.

—The form of house does not signify a great deal, but if a choice can be made I would choose the span-roofed form, running north and south. The only way to produce them in quantities for the market is to grow the plants well. It would be cheaper to purchase young stock now, and grow the plants on until they were ready for layering. The size of flower-pots must be determined by the size of the plants. Large specimens producing many flowers I have seen growing in 10-inch and 11-inch pots. Young plants a year old might be grown and flowered in 8-inch and 9-inch pots, while 7-inch would be quite large enough for last year's layers. As to the time for repotting Carnations or any other plants, an experienced cultivator can tell by the state of the roots. He waits until the flower-pots in which the plants are growing are inefficiently filled with roots, but not so much as to be what gardeners term pot-bound. My Malmesdon Carnation layers are potted early, sometimes before the middle of September. I plant a single layer in a large sixty-sized flower-pot, and they are ready to repot into 7-inch early in February. The same plants will need a 9-inch or 10-inch flower-pot next year; small ones may take an 8-inch only, but if all the layers are taken off the old stool will not be worth keeping.—J. D. E.

3133.—Violets for autumn and winter.—I wish "Constant Reader" to try the Blue Neapolitan Violet again. I suppose his plants are in the frame, planted out. Take the young-growth in April, with root, too, and plant 1 foot apart, and in leaf-mould 1 foot to

2 feet deep under a south wall, or where it is shaded, and water when dry, and when they have made young crowns, peg them down, five or six of them, and take off all runners after that time, and take them up in September and pot them in 32-sized pots; put the old crown in centre, and the young ones round side; use all leaf-mould riddle for potting, and put them in a frame where they will get all the sun in winter, and close to glass when lights are on, and protecting from the frost with whatever you have got—coll put at the side will do—and you will have plenty of Violets.—W. R.

INDOOR PLANTS.

ARISTOLOCHIAS.

I AM asked to name some family of plants that will grow well in a rather large stove, plants that will grow and flower freely, and have a distinct and tropical effect? Now I do not know a genus that has a more quaint and majestic appearance than the present one now under consideration; but they require a warm tropical temperature to grow them successfully, for they do not develop their charms in anything like such a marked degree in a cool stove. These charms are, however, somewhat handicapped by the strong and unpleasant odour emitted by the flowers of most of the species, but which is not perceptible when the plants are upon the roof of what my correspondent calls a rather large stove; of course, the stove is not to be covered with these plants entirely, for there are plenty of such things as *Bignonia*, *Bougainvillea*, *Clerodendron*, *Dipladenia*, *Passiflora*, and many others which will do equally well and flower profusely if used alternately with them; but now I am about to recommend some of the numerous family of the *Aristolochias* or Birth-worts as they are called. One species appears to be a native of Britain; although modern authors say it is not indigenous, yet the older writers make no doubt about its being a native plant. This is the *A. Clematites*, which is an upright growing shrub, growing about 3 feet high, having dark-green heart-shaped leaves some 3 or 4 inches across. The flowers are crowded, but they are not showy; still, it is a nice plant to have in the border; whilst *A. Sipho*, a large-leaved American species, is frequently to be found in gardens, where it is useful and ornamental as a deciduous climber. However, we must now turn to the stove climbers of strong growth. Amongst these I would recommend *A. ornithocphala*, which is a sturdy plant which will be found specially suitable to my enquirer, and it makes an invaluable plant for covering a pillar or rafter, the leaves being large, measuring some 8 inches or 9 inches across, heart-shaped, and deep-green. The flowers are curiously shaped, the tube being white or creamy-white, streaked and veined with deep purplish-brown; beside this, it has a large two-lobed appendage, something resembling a wattle, which is white, beautifully setted with reddish-purple. *A. labiosa* is another plant, with more uniform leaves, and with a similar but smaller flower; whilst *A. gigas*, by some called *grandiflora*, has long heart-shaped leaves, has large flowers having a ground colour of creamy-yellow, mottled, and blotched with deep-purple; it has a long toil in front. I will say nothing of the gigantic-flowered kind from Western Africa called *Goldiana*, which has a tri-lobed bloom which measures 2 feet or more across, but will here confine my remarks to a few of the smaller-flowered kinds, which may be grown by anyone having a small stove, in which they form very beautiful ornaments, and I really do not think a prettier plant could be found than *A. elegans*. This is a plant that was introduced to our gardens some few years ago by Mr. Bull, of Chelsea; it is a slender climbing plant, having ovate or heart-shaped leaves, which are slightly glaucous beneath, pale-green above, the flowers borne upon a long, slender stalk; the tube is suddenly bent upwards, and forms a cup-shaped limb some 2 inches across; the ground colour is creamy-white, having a rich, golden-yellow eye, round which is a rich, dark, velvety zone, and beyond this is much-branched markings of dark purplish-brown. These flowers are quite destitute of the strong odour usually found more or less in all the *Aristolochias*. *A. Duchartrei* is a somewhat similar flower, but the plant is very different; it is a climber, but the flowers are pro-

duced upon the old wood, having the usual bent tube and spreading cup-shaped limb, with a creamy-white eye, which is the ground colour of the flower, beautifully and regularly modelled with velvety blackish-purple. This plant is better named *Ruiziana*. I am told it was introduced by M. Linden from the Amazon. *A. tricaudata* is not a climber, and it has oblong leaves of a deep-green; it produces single flowers from the lower joints; those have the bent tube so peculiar to this genus, which develops into a wide limb, which is of a very deep-red or dark-purple. It is trilobed, these lobes being some 4 inches long; it also is quite destitute of any odour. There are many other of the small-flowered kinds exceedingly interesting and beautiful; but I think I will draw this to a close by noticing just one more species, and that is the farical plant called *A. ridicula*, which has a head and pair of ears which stand up and correspond with the head of a mule in its various phases of temper; it has creamy-white and purple markings. For the strong-growing climber it is much the best system to have them planted out, confining the roots somewhat by a bricked-up partition. Drain this well, and the soil best suited to them is a mixture of good turfy loam and brown peat in about equal proportions, the whole to be made fairly sady. The latter and small growing kinds may be grown in good sized pots, and they will flower freely, and after a time a surfacing of loam mixed with sheep's-manure will be found a great restorer. Nothing more is necessary, saving an abundant supply of water from the syringe to keep down red-spider and thrips, and also to their roots during the growing season. During winter they may be kept rather short of moisture with advantage. J. J.

3212.—Greenhouse flue.—Yes, you can do as you propose and heat the pit at the same time as the hooc if you use a damper in the way you propose; but the flue in the pit must be on the same level as the old one, and the chimney nearly, if not quite, the same height. With having the flue on the same level and the new chimney the same height as the old one, you may possibly be able to heat both the house and pit at the same time without using the damper; but I cannot say if the heat would divide itself in this way. I should be glad if you would try and kindly let me know the result. I know that the heat will return on nearly the same level, and even dip down under a doorway if the chimney is high enough; but to provide the possibility for the heat to divide at a certain point is an idea quite new to me.—J. C. C.

2356.—Plants on the back wall of a vinery.—You say that the house is cold in winter. If by that you mean it is not heated in frosty weather you must not plant anything that is tender, and although the *Lapageria* is nearly hardy it is doubtful if it would live through a severe winter in such a position. All the other plants you mention will answer your purpose, and if the house is not heated in frosty weather I advise you to plant the *Passion-flower* *Constance Elliott* in the place of the *Lapageria*.—J. C. C.

—The house being quite cold in winter will limit the selection, but *Marchal Niel* and other *Roses* will do well. *Passiflora Constance Elliott* and the *Lapageria* might do, though it is just possible the house might be too hot in summer for the *Lapageria*. *Fuchsias* would probably get out down with frost in winter, but if the roots were protected, they would break strongly from the bottom. *Camellias* would succeed.—E. H.

—For such a position there are no plants to equal *Camellias*, *Oranges*, *Lemons*, and others of the *Citrus* family. The shade of the vines overhead does not suit *Roses*, and the heat in summer will be too great for *Lapagerias*. *Laquila grandiflora* would do well if it could have heat in the winter, but under the circumstances I should plant *Camellias* almost exclusively.—B. O. R.

3184.—Culture of *Cyperus alternifolius*.—This plant is very easily managed, the chief points being a well drained porous soil, plenty of moisture both at the root and in the atmosphere, and a generally warm temperature. Seedlings grow well in a mixture of peat, loam, leaf-mould, and sand, sifted rather fine on the surface and well drained. If they come up thickly, prick them off 1½ inches apart, in boxes; but if tolerably strong, they may be transferred directly to thumb-pots. Shift them on subsequently as required. Shade from bright sunshine must be given at all times.—B. O. R.

—This plant is easily grown either from seeds or by division of the plants. There is a

a variety with variegated leaves; the stems and leaves are streaked with white. They are excellent window plants, and are grown in thousands by the market gardeners. The green-leaved variety is generally raised from seed, sown in pans of good potting-soil, sandy loam, and leaf-mould. The seed vegetates in a little heat, and the plants certainly do best when grown on in a moderate hot-house. Prick the young plants out into pans, and ultimately pot them off singly into flower-pots.—J. D. E.

3238.—Carnation cuttings.—Plant out the cuttings if well established in a properly prepared bed, made up of good loamy soil mixed with a little wood-ashes, or similar material. Take care of wireworms, and it is not wise to plant, for instance, on quite fresh ground, as we have seen splendid stocks of Carnations succumb to this insidious pest. Wireworms seem to have a special liking for the fragrant flower. You cannot expect great things from the plants this year, but if all goes well they will be healthy examples next season. From what, however, I can judge, the cuttings have still to be struck. Get them in at once, inserting round the sides of 5-inch pots, plant with a light soil and well crooked, give them a gentle bottom-heat, and when rooted pot off.—C. T.

—It is late now for these, unless they are of the tree varieties, when they will come in nicely for flowering next winter, and cuttings rooted now could not be expected to bloom this year to any extent, if at all.—B. O. R.

3224.—Primulas for spring.—A good strain of the Chinese *Primulas* (*Primula sinensis*) sown towards the end of April will bloom in spring (for winter blooming sown now). *Primula obconica* sown now will commence blooming in autumn, and flower all winter and spring in a warm greenhouse. The plant has a bad reputation, though I have never met with it, and imagine it is not common.—E. H.

—I presume you mean Chinese *Primula*, and you may sow seed in the early autumn, say August, reckoning about six months with proper treatment from the time of sowing the seed until the plants bloom. You will find information upon the treatment of the plants after sowing in *GARDENING*, Feb. 25, p. 741, and March 4, p. 112.—C. T.

3246.—An Azalea shedding its buds.—It is not so usual for *Azaleas* to shed their buds as it is for *Camellias*; but *Azaleas* will do it if they receive a very serious check to their development. Some persons keep their plants far too dry at the roots in winter, and as the compost in which they are grown usually consists of sandy peat, over-dryness is more injurious, owing to the difficulty to thoroughly wet such soil; and the fine and very numerous hair-like roots of the plants are killed. Water applied too freely thereafter does more harm than good, causing a check which will often cause the flower-buds to drop off. The Indian *Azalea* is even more hardy than "*Geraniums*," as far as injury from frost is concerned; but exposure to a continuous cold draught of air would injure the *Azalea* first, and cause both buds and leaves to drop off. I would put down the cause either to sudden checks from the plants being exposed in cold draughts, or from careless watering.—J. D. E.

3233.—Primulas from seed.—If you can get the seed ripe by the beginning of next August, and it is sown at that time, the plants should flower in the following spring; but in a general way the seeds do not get ripe early enough to produce flowering plants the same year. By fertilizing the flowers of *Primulas* a greater number of seed is produced. You may, however, get a few seeds if you place the plants at once on a light, airy shelf in the greenhouse. I have known the plants ripen seed without being fertilised in a sunny window, and I have seen hundreds of plants at the Lanport nurseries placed out-of-doors in the month of May, with only a canvas awning suspended over them, with a good number of seed-pods on each plant. In this case the insects did the fertilising part of the business gratis.—J. C. C.

—The seed seldom ripens before July, and then, even if sown immediately, the plants are too backward for anything but late spring flowering. By pushing the seedlings on briskly I have had good plants in time to save seed from again the following spring, but as a rule the seed sown in this summer, is kept over until the following spring. *Primulas* do not set well before March at the earliest, so that for this

purpose it is no use to have them too forward. The flowers must be fertilized on all bright days with a camel-hair brush, or there will be little or no seed, especially on the choicer varieties, and the plants ought to stand on a shelf near the glass in a sunny and moderately warm structure.—B. C. R.

— Seeds of *Primula* in blossom now will be ripe in time for sowing to bloom next spring. I have plants in bloom now the seeds of which were taken from plants in blossom later than this last year. You will get more seed if you fertilize with the camel's-hair pencil. Do it about midday, when the pollen is dry.—E. H.

— The seed of the *Primula sinensis*, (the Chinese *Primula*), sown this year, will be ready in time to sow and produce flowering plants for next season. The seed is produced sometimes without any attempt at fertilization artificially, but if the flowers are artificially fertilized the amount of seed obtained will be largely increased. Sow the seed as soon as it is ripe.—J. D. E.

GREENHOUSE RHODODENDRONS.

The kinds of *Rhododendron* that will thrive under greenhouse treatment are now numerous. Among them are several species, such as the magnificent *R. Nuttalli* from Booten, which attains a height of 20 feet or 30 feet, *R. Gibsoni*, a compact bushy-habited sort from Khosaea, *R. arboreum*, from Nepal, *R. Dalhousiana*, from the Himalaya, *R. jasmini-*

plants altogether under glass for two years, giving ordinary greenhouse treatment, after the grafts have got a good start in the warmth already advised; this is requisite to get them on in size. Afterwards they will be better out-of-doors in the summer. They do best in good turfy peat, to which add some sand. Large-growing kinds like *R. Nuttalli*, as they get big enough to require it, must have large boxes or tubs to grow in, or better still, be planted out.

INSECTS.—*Rhododendrons* are not much subject to the attacks of insects, but, grown under glass, they frequently get affected with scale or mealy-bug, for which syringe freely with water and sponge with soap and water.

The undermentioned are desirable sorts: *R. Countess of Haddington* (blush-white), *R. Countess of Sefton* (white and rose), *R. Dennisoni* (white and lemon, very fragrant), *R. Duchess of Edinburgh* (bright orange-scarlet), *R. Duchess of Sutherland* (white, flowers fringed), *R. Duchess of Teak* (yellow, tinted with scarlet and rose), *R. Lady Skelmersdale* (pure-white), *R. Maiden's Blush* (blush-white), *R. Pink Beauty* (white and pink), *R. Princess Alexandra* (pure waxy-white), *R. Princess Alice* (white, tinged with pink, fragrant), *R. Princess Royal* (rose colour), *R. Prince of Wales* (orange-red), *R. Purity* (pure white, very fragrant), *R.*

is dry, water before sowing the seed, then cover each pot with a square of glass large enough to keep the seeds quite close, and set in a sunny window every morning. Reverse the glass so as to bring the damp side to dry. Whenever water is required, dip the pot up nearly to the rim in a pail of tepid water, and as soon as the plants appear ventilate only a little at first, increasing the size of the openings almost daily till the plants can bear full exposure. If the plants are to be grown in pots, prick off very large enough to handle. If to be planted in the borders, harden off gradually till the weather is suitable, and then prick out in beds.—E. H.

3036.—Treatment of Cyclamens.—When *Cyclamens* pass out of bloom, they should be placed on a shelf near the roof-glass of a greenhouse until the weather is mild enough for them to stand in garden-frames. They should be kept moderately dry at the roots during summer, and when it is time for them to start into growth in the autumn, they should be repotted and may be kept in the garden-frames until the end of September, when it will be time to place them in the greenhouse again. The *Erica*, which has just passed out of bloom, is probably one of the herbaceous section, *E. hymalis*, and it should be cut down, and when it has started to grow repeat it. This also will flower well next season.—J. D. E.

3139. — Oleander not flowering.—Your plant probably requires repotting, as this will account for the flowers dying away, or the room is not suitable. The best place to grow *Oleanders* in is a greenhouse. We should advise you to look to the roots, and if a shift into a larger size is desired do this in the spring, using a soil composed of three parts good loam, peat one part, and a part of well-decayed manure. Mix with this preparation sufficient sharp silver-sand to make it moderately light.—C. T.

3180. — Bryophylla calycinum.—This is really a stove plant, but it does not need a very high temperature to grow it. I cultivated plants of it for several years as a curiosity, but after this was gratified I turned them out. The plants spring from the notches of the leaves, and these being succulent, they do not shrivel when broken off from the plant. If the leaves are laid on the surface of the soil the plants will soon appear, and at each notch on the edges of the leaves a tiny plant will form, which in time will root into the soil. Well-drained pots of sandy loam suite it very well, and the leaves being succulent, water should not be applied too freely.—J. D. E.

3198.—Slugs in a greenhouse.—Water with lime-water, or visit the house at night with a light, when they are feeding, and capture them. Perseverance in this way will soon clear them off.—E. H.

— I am afraid there is no other remedy but catching the slugs in such a case as yours, and the only way to do this is to search for them at night by lamp-light. In the day lay down two or three Cabbage or Lettuce-leaves and examine them at night, repeating your visits until you find there are no more of your enemies. I am suffering just now from a plague of woodlice amongst my Ferns, and to get rid of them I search for the insects every night and kill them. I know of no other means of getting rid of them.—J. C. C.

3151.—India-rubber plant.—This is a very common complaint, but it is difficult to assign an exact cause with any degree of certainty. Errors in watering frequently result in an affection of this kind; if either too much is given, especially in cold weather, the soil becomes sour, and then the health of the plant suffers; while occasionally the soil may become excessively dry, and then the fine feeding fibres perish. It may be only the natural decay of the lower leaves, as after the stem of any plant, however healthy, attains a certain length the lower leaves are certain to fade and fall. Nothing can save the leaves that are already affected, but if the soil should be found to be sodden and unwholesome, the plant had better be carefully repotted, and kept in a close, warm house for a time. Even this will probably have the effect of bringing off a few more leaves.—B. C. R.

A greenhouse Rhododendron.

florum, from Malacca, and *R. javanicum*, a Java species, from which have sprung the large number of beautiful hybrids, now coming so largely into use for conservatory decoration. The free-growing habit of these hybrids, and their equally free disposition to flower—often two or three times in the year—combined with the beauty of their flowers, go to rank them with the most desirable plants for the decoration of cool-houses. The hybrid varieties possess a much better habit than *R. javanicum*, which is a determined spare erect grower, not disposed to branch out. The mode of propagation best suited to the hybrid sorts is grafting on such of the seedling varieties as possess a free, vigorous constitution. The stocks require to be raised from shoot cuttings in the ordinary way, and grown on in 6-inch or 8-inch pots until large enough for grafting, when they may be headed down to within 5 inches or 6 inches of the pots, and the grafts, which should consist of pieces of the preceding year's shoots, inserted. The work ought to be done in the winter, and after grafting the plants should be placed in sufficient warmth to start them into growth. When some progress has been made the points of the shoots must be pinched out to induce the lower eyes to break so as to furnish the plants with side-branches. After this the treatment is simple, merely giving pot-room as required. These *Rhododendrons* do not want so much pot-space as many things. It will be well to keep the

Rosy Gem (white, pink, and rose), *R. Taylor* (pink), *R. Thomsoni* (scarlet), *R. Vestchianom* (yellow and white). The following species are fine kinds: *R. arboreum* (scarlet, Nepal), *R. argenteum* (white, with black spots, Himalaya), *R. Aucklandi* (white, Himalaya), *R. Dalhousiana* (white, Himalaya), *R. Falconeri* (red and white, Himalaya), *R. Fortunei* (white, China), *R. Gibsoni* (white, Khosaea), *R. jasmiflorum* (white, Malacca), *R. javanicum* (yellow, Java), *R. Nuttalli* (white and yellow, Bootan). B.

3050. — Plants from seed.—It is quite possible for a beginner to raise healthy plants from seeds in a house without greenhouse or frames. There are some things that might fail; but a fair amount of success would be obtained if he went the right way to work. Do not start too early; end of February or beginning of March will be better than earlier. The pots or pans must be well drained with broken bricks or charcoal, or something equally porous. Three inches of such materials in the bottom of 6-inch pots will not be too much. In the drainage place some of the rough soil which has been sifted from that intended to sow the seeds on. Fill the pots moderately firm to within an inch of the top. Sow the seeds thinly, and cover about an eighth of an inch—not more. Very small seeds will not require quite so much covering. If the soil

is to be sown on a wall.—The *Hellebore* will do no good in an unheated house. The winter will

OUTDOOR PLANTS.

ROMNEYA CULTRERI.

I AM asked by a resident near Exeter what chance he has with this plant if he plants it outdoors near a west wall? It is the very place I should choose for it above any other. Whilst being so well in the West, you should have an excellent chance of its becoming a beautiful feature in your garden. Plant it if you can in a well-drained spot, using for soil sandy peat, with a small portion of light loam. I have not had much experience with this plant, but should like to see it become more frequent in our gardens. The flowers are very thin, and they do not lose the peculiar crumpled appearance, like a newly opened bloom, yet they last well for several days; they also are very ornamental when cut. They are soft creamy-white in colour, the centre is composed of clear yellow stamens, and it yields a delicious perfume. I certainly strongly advise the plant to be put into the position named. J. J.

3197.—**A small garden.**—You certainly will not be able to get many crops in your little garden if you wish to have flowers. Your query is not very plain. If you need flowers you may grow many kinds. The first thing is not to cut up the ground with two-hoed walks, as the fashion is—walks that are utterly useless, as one would suffice quite as well. Keep the walk on the outside, so as not to break up the garden, and let it be as narrow as possible. A good gravel path is as satisfactory as anything, and you could lay down the centre of the garden with Grass-turf, making one or two small beds for the growth of Roses or hardy plants. Run a border round against the fence or wall, or you can dispense with the central beds and plant instead the two Apple-trees that you wish to have—Cox's Grange Pippin and Lane's Prince Albert being good kinds, the former for dessert, the latter a kitchen kind. They would look pretty when in bloom in the spring, and leafy throughout the summer. If you adopt this plan, keep the hardy plants, Roses, annuals, &c., to the border at the side. It is too late to plant bulbs now, but in the autumn you can put in good clumps of the best *Daffodils* (as *Horsfieldi*, the *Poet's Narcissus*, and *Emperor*), *Tulips*, *Ilycinths*, *Chionodoxa* or *Glory of the Snow*, *Scillas*, *Winter Aconites* (very pretty, peeping up through the ground in February, the flowers yellow), *Crocuses* (both spring-flowering and the beautiful autumn-blooming *C. speciosus*), *Fritillarias*, *Crown Imperials* in particular, *Snowdrops*, *Spanish and English Irises*, *Lilies*, and *Grape Hyacinths*. Then you can have good masses of such spring or early summer-flowering hardy plants as the *Adonis vernalis*, *Rock Madwort*, *Alyssum saxatile*, *Arahis alhida*, *Thrift*, *Doronicum caucasicum*, *Helleborus guttata* and *H. orientalis*, *Iberis* or perennial *Candytuft*, *Spring Snowflakes*, *Leucorum vernum*, *Forget-me-nots*, *Renunculaeae*, *Saxifrage*, and *Pensies*; whilst for autumn there are the beautiful perennial *Sunflowers*, *Achilles*, *The Pearl*, *Alatrorium aurea* (a vigorous growing plant), *Anemone japonica* and its white variety, the beautiful Japanese *Windflower*, *Michaelmas Daisies* of sorts, *Early Chrysanthemums* as *Mme. Desgranges*, a few good hardy kinds, several of which were named in GARDENING, Feb. 18th, page 723, *Funkias*, *Helenium autumnale*, *Evening Primrose*, *Sedum spectabile*, and *Herbaceous Ploexes*. You must not forget *Primroses*, *Polyanthuses*, *Sweet Williams*, *Antirrhinums*, *Stocks*, and other homely flowers—at any rate, the above will make a good commencement, and at this season you can sow annuals, not sowing the seed too thickly, as the practice is with amateurs. Lists of the best annuals have been recently given. If you are not situated in the middle of a smoky town grow a few *Roses*, and cover the wall with good climbers, such as *Clematis Jackmanii*, *Veitch's Virginian Creeper*, the *Pyraeanths*, *Honeysuckles*, a good *Ivy*, as *Emerald Gem*, *Jasminum nudiflorum*, and *Wistaria*. You will not have space for many shrubs and trees, but I will name six of value—the *Rose Acaia* (*Robinie hispida*), *Weigela* (a beautiful, free-growing and flowering shrub), *Fuchsia Riccartoni*, *Guelder Rose*, *Lilac*, and *Philadelphus microphyllus*. You can do nothing else, as you will see many charming things in ger-

dens if you observe that may be noted to get for your own little place. I may remark that it is essential to have good soil. Builders' refuse will not grow plants.—C. T.

3185.—**Forget-me-not.**—The best *Forget-me-not* for garden culture is *Myosotis disitiflora*; the flowers are a deep sky blue colour, and are abundantly produced in May. There is a variety with white flowers, but the blue one is the original colour and the best. It is best to propagate it from seeds, but seeds sown now would not produce plants to flower this year in May, but they would do so abundantly next year. I have thousands of plants of it left to run wild in a border that is never dug, and they seed and increase abundantly of their own accord. The seed may be sown now or later. I would sow it in May and look for a grand display of bloom next year. The white form is very pretty and should also be grown. There is also a form with variegated leaves, which was introduced under the name of *Myosotis distiflora elegantissima*; the leaves have a distinct white margin.—J. D. E.

3242.—**Shortia galacifolia.**—It is rather early yet to write of this plant, and those plants I have seen at shows have not been grown throughout the year in the open air. It is a delightful flower, net unlike an enlarged bloom of the *Soldanella*, of the purest white, with a suspicion of rose in it, and carried on stems about 6 inches in height. Then one gets a fine feature in the bronzy-red leaves that change to quite a crimson colour. It is almost worth growing for the sake of its crimson foliage in the winter months, and this is intensified when the plant is grown away from shade. It will succeed either in light loam or peat, but the former is better if the best colored leaves are derived. I have heard of plants dying, but in the neighbourhood of London it has lived out over a year. It is unquestionably one of the most beautiful things we have received from North America. The *Heuchera sanguinea*, as far as our experience goes, will live through ordinary winters. It likes a sunny well-drained border, the soil not too heavy, and then makes a delightful show of its scarlet or crimson flowers. It is very pretty also grown in pots for the greenhouse. Unfortunately it does not come very true from seed. They are often less rich in colour than the type, and more straggling in habit, although they bloom very freely. The species does not always continue to bloom well when planted out. *H. sanguinea* is a charming plant, the flower-stems very graceful, and rising about 2 feet in height.—C. T.

3248.—**Seeds of hardy perennials.**—The ground must be thoroughly prepared. I have generally tramped up a piece of land in autumn or during winter and left it lying rough till spring. I consider April is the best month for sowing most things, and if the land has been properly prepared there is no necessity to cover with anything; but I have used when necessary a compost of charred refuse, burnt earth, and sandy loam, all well blended by being passed through a half-inch sieve. This is used in special cases, but for the most part the seeds are sown in drills about half an inch deep, and covered with the ordinary soil. Such situations can be selected for those which grow naturally in such positions where it is intended to naturalise certain plants without the trouble of raising them elsewhere. Spots of suitable soil can be trenched and cleaned, and the seeds then sown in drills. I prefer the drill system under all conditions, as it saves so much trouble in keeping the plants clean the first year. Whatever is done afterwards, they should be kept clean the first year and the plants properly thinned according to the space each will require.—E. H.

3188.—**Culture of Pinks.**—Show Pinks should have been planted in autumn to have the flowers fine and the colours true and pure. The usual way of propagation is from cuttings or pipings of the young side shoots just after flowering. They will strike quickly under glass, and the choice varieties are generally struck in that way in light sandy soil. But the common hardy sorts (*Border Pinks*), such as *Mrs. Sinkins*, may be pulled to pieces any time during autumn, and planted either in patches, or a dozen in a pot, or in beds from 6 inches to a foot apart. The following are good

varieties, including the two classes: *Bertram*, *John Ball*, *Godfrey*, *Lord Rosebery*, *Master Merry*, *Wm. Paul*, *Emily*, *Ade*, *Derby Day*, *Lord Lyon*, *Firoman*, *Modesty*, *Mrs. Sinkins*, and *Hor Majesty*.—E. H.

3257.—**Water plants.**—I might give "*Pay de Galle*" a long list of things that would flourish in such situations as he names, but perhaps it will be of more assistance if I throw out a few suggestions. He seeks bold effects, therefore it must be through the medium of fine things planted on a large scale. First for the waterside: One of the earliest flowers coming with the *Giant Ringcaps*, and belonging to the same family is the *Globe-flower* or *Trollius*; it loves the water-side. *T. europaeus*, *asiaticus*, and *Dahuricus* are good kinds, the last-named especially, which attains 3 feet in height. *Spiraeas* are charming, too, especially *vonusta* and *palmata* and its varieties. *Day Lilies* love the water-side, and, then, *Irises* are a host in themselves. Take the Japanese species, *I. Kamperi*, and plant it by the hundred. If it does well you will wish for nothing better. The *Giant Knotweeds* (*Polygonum cuspidatum* and *sachalinense*) are delightful, their long arching wands wreathed in blossom in autumn, and through the winter up to now the nut-brown, though dead, stems stand picturesque through the winter. I might name many more things, but such as are here can be bought tolerably cheap by the score or hundred. As regards the ground beneath trees, *Primroses* often flourish very well if there is a fair depth of soil. I should procure some of the species which can be obtained cheaper and in quantity. The situation, in some respects, no doubt governs the choice of plants. If the *Nettles* provide useful covert, why not seek the same shelter for game among useful and pretty plants, first eradicating these noxious weeds? If some of the *Giant Grasses* would thrive there they would be charming. The *Sea Lyme Grass* (*Elymus arenarius*) is most charming, of a rich glaucous colour, and will grow anywhere, according to my experience, in sand or clay, and affords excellent cover. Then there is *Pampas Grass*, if hardy enough, but in any case *Eulalia japonica*, which is much hardier, will succeed, and though it does not flower so freely, it is tall and graceful. *Arunda conspicua* should be tried. This suggestion, however, is solely ruled by the situation. Another idea occurs which I have been carrying out quite recently. There was *Grass* honest *Oak-trees*, margining a walk. It was dug over except just round the tree-stems, and large carpets of *Ivy*, in many varieties, the shoots being pegged down over the ground, and at the same time interspersing with the *Ivy*, to come above it, *hard Ferns*, *Solomon's Seal*, and *Iris foetidissima*, a charming plant for the shade anywhere. *Primula japonica* does very well in partial shade in the Grass, and it is just possible this might suit some of the places. In a Cornwall garden they are naturalised by thousands.—A. H.

—There are many plants that you could grow by the edge of the water. *Primula japonica* (the *Japan Primrose*), is a very free plant for the purpose, and it will get practically naturalised, seedlings springing up freely. Get a good colony of it, and there is a great variety in the flowers, and they vary from the deepest-crimson to even salmon-rose, the leaves large and vigorous. The flowers are borne tier or whorl position, and display is maintained over a long season. In the subdued shade of a wood, or by the stream-side, it has a fine aspect, and loves moisture. Then you can have the charming flowering *Rush* (*Botanum umbellatus*), as it likes a rich moist soil, and in the collection could also be included the bright, rose-coloured *Primula rosea*, *Cathas* (or *Marsh Marigolds*, known also as *Kingraps*), and of these there are many varieties, the double kinds, each flower like a golden rosette, being very effective. *Irises*, such as *I. sibirica*, are suitable; in fact, all the beardless forms, and you could get a good growth of the Japanese *I. Kamperi*, which delights to be by the margin of a pond or stream. There is great variety in the flowers, varying in colour from white through many shades of purple. The broad segments showing up well in August, and the vigorous growth is in itself ornamental. The beautiful *Globe-flowers* I have mentioned succeed well by waterside, and you could vary the effect by having snob

Ferns as the Royal Fern (*Osmunda regalis*), *Struthiopteris*, &c.; in fact, all the hardier kinds. A very pleasing plant thus placed is *Carex pendula*, which looks especially well if on the Grass that slopes down to the water's edge. I remember it finely grown thus in the late Sir S. Macleay's garden at Bletchingley. Remember our common yellow Iris (*I. pseudocorus*), which is very charming near water. I have seen the Oswego Tea (*Monarda didyma*) bloom remarkably well by the water's edge; also the large white-flowered *Trillium grandiflorum*, though this belongs more to the bog garden. *Lobelia fulgens*, Queen Victoria or Firefly, may be expected to bloom well, as they prefer moisture; also Orchises of various kinds. This list will form the basis of a respectable collection. You cannot expect showy flowers under the shade of trees, but you may carpet the surface of the ground with Ivy, selecting good strong plants of the Irish Ivy, or Emerald Gem, and pegging the shoots down to the soil, and if the shade is not too dense, try the Spanish Squill, or naturalise Blue-bells. Under the dense shade of trees it is hopeless to think of getting an abundance of flowers.—C. T.

3202.—**Culture of Christmas Roses.**—Plants growing and left to open their flowers in the open are not nearly so satisfactory as those which expand their blossoms under cover. It may be only a cold frame or a hand-light, yet they are kept clean and free from frost, which does much damage to the opening flowers. Christmas Roses do not like their roots being continuously interfered with, as in the case when the plants are dug up and placed in pots or tubs to enable their blooms to be brought on more rapidly. If the plants are so arranged in planting that a frame can be placed over them at the end of October, flowers will be ready for use by Christmas, and will last quite fresh and are always clean until the end of February. Not only is this plan so much better for the welfare of the plants, which increase every year, but the labour is minimized. A border with an eastern aspect suits these plants well; the border is not so liable to be dug during the summer as though it were a southern exposure. A moderately light sandy loam is favourable to a free growth, but where the soil is heavy and retentive it will be necessary to remove the greater part of it, substituting and mixing with it peat, leaves, charcoal, and old potting soil, first breaking up the subsoil to a depth of 2 feet, to admit of a quick percolation of the surplus water from heavy rains. If the plants are small they may be put out 2 feet apart, or so arranged that a frame will enclose them without crushing the leaves or crowns. Over the surface soil spread a 2-inch thickness of partly-decayed horse-manure, which will, in the event of dry weather settling in, prevent the escape of moisture from the soil. Give abundant supplies of water to the plants during the summer if this be hot and dry; drought at the roots is detrimental to a free growth, and without this a full crop of blossoms cannot be had. When the frame is placed over the clumps at the time named no more water will be needed; but should there be any signs of slugs troubling the plants, a dusting of soot on the surface will drive them away. This stimulant will not affect the blooms either, the surroundings being dry, and the flower-buds not yet above the surface. Keep the frame closed or open, according to the time the flowers are required to expand. In the case of frost cover the glass with mate sufficient to protect the blooms, giving air on all favourable occasions to maintain a dry atmosphere, which is less likely to discolour the flowers in frosty weather. When all the flowers have expanded the lights should be taken off daily to gradually inure the plants to cooler conditions, removing the frame altogether in a week or two. Cut off any old flower-stems, but not any of the leaves, except, of course, the dead ones; seldom these are visible, the same leaves remaining on the plants for a number of years. Repeat the mulching and watering process every year. Our plants treated in exactly the same manner have been where they are now for the last ten years, and are annually a great success. They promise the same for many years to come.—S. P.

321.—**Plants on a lawn.**—There is no better way than carefully and patiently digging them out with a tool made for the purpose, which may be obtained from any ironmonger. The ground is not now, and they may be extracted easily. It is no use to cut them off.—E. H.

FRUIT.

CHERRIES AND THEIR CULTURE.

TAKING the earliest Cherries first, the one I would recommend is Overroor Wood, which is a most prolific kind, and bears medium-sized fruit of a pale yellowish-white, anflused with colour on the side next to the sun, the juice, of which this Cherry is full, being very sweet and delicious. The next to ripen after this is the Frogmore Bigarreau, which is a little larger and brighter than the foregoing, and, like the old Bigarreau, of exquisite flavour. Black Eagle and Knight's Early Black come in quickly after, the first-named being a small kind, with very black, shining fruit, that is sweet and agreeable; and Knight's is the same in colour, but much larger, and not equal in flavour, as it is more fleshy and less sweet in the juice. To come in after these none are equal to the Elton, which is the most showy and best of all Cherries, as the fruit is large and high-coloured, and very rich in the flesh. As a black companion to this, ripening at the same time, the Tartarian is the best, the fruit being large and conical, and deep blue-black in colour. Although there are many others of the desert kinde, these mentioned above are the most distinct and desirable, and for cooking, till the Morello come in, none are equal to the May Duke, which is a prodigious

Cherry "Belle de Montreuil."

bearer, and the fruit will hang a long time. Belle de Montreuil (here figured) is an excellent mid-season Cherry for a wall.

THE MORELLO is quite indispensable, and is the most serviceable of all Cherries, as it may be used in such a variety of ways; and its season is a prolonged one, as by keeping the trees dry the fruit will remain sound and good till very late in the autumn, and the longer, in reason, it remains, the better it is. To have it to the period referred to it is necessary to train the trees to a wall or fence, that with a north, north-west, or north-east aspect being the most suitable; and if the young shoots are allowed a little freedom to grow out as breastwood, much time will be saved by tying them in, and they will bear heavily and keep cleaner and more free from insects through the washing they get. Morello Cherries also do remarkably well grown as dwarf standards or loose espaliers, with the main branches just held to strained wires, which is a good plan of growing them, as they may be protected easily when in flower or fruit—in the first place, by sticking a few evergreen branches along their sides, and in the latter by dropping nets over the tops. All Morello Cherries require in the way of pruning, when grown loosely, is just an annual thinning-out to prevent them becoming too dense, as, unlike the desert sorts, they must not be spurred in or have the shoots stopped, but left to grow full length. The most favourable situation for the

but it is always advisable to have some in different aspects, as when frosts come, with wind from one quarter, and kills the blossom, it often escapes in the other, and not only that, but a longer succession of fruit is maintained. To keep the spurs close to the wall, which is the only way of taking full advantage of the shelter, the shoots the trees make during the summer should be pinched back about the middle of July, when they will form fruit-buds at the base. Although Cherries do fairly well in almost any soil, that of a light sandy nature suits them best, and, therefore, in planting the young trees they should be started by having a barrow-load or so of sharp turfy loam to each, in which they will root and soon make some fine shoots. These ought to be laid in full length, and not stopped or shortened at any time till they have filled the allotted space and met the others trained at their sides. For destroying green or black-fly on the tree, to which insects they are very subject when the shoots are young and tender, there is nothing so safe as Tobacco-water, in which the points may be dipped.

B.

CANKER IN APPLE-TREES.

WHILE I do agree with most of "H."s" article on the above subject in GARDENING, Jan. 14th, p. 657, Vol. XIV., I must take exception to one or two items contained therein. I should also like to make a few observations derived from some years' practice with Apple-trees. In the first place, "H." mentions the advios often given to head old cankered trees and graft them with healthy scions of some other free-bearing variety. I have done the same with the best of results and have often seen it done in old orchards with similar success. Why is this? The reason is not far to seek. First of all the old cankered tree was probably one of those notorious varieties to canker, such as Ribston Pippin, Lord Suffield, Reinotte du Canada, Sturmer Pippin, Duchess of Oldenburgh, Sterling Castle, J. A. Fish, Achmasd Kernel, and in some soils, Cox's Orange Pippin, and King of the Pippins will also canker badly. All the above are notorious for canker more or less. Very well; probably the old cankered stumps were grafted with such sorts as Peasegood's Nonsuch, Potts' Seedling, The Queen (Saltmarsh's), Worcester Pearmain, Small's Admirable, Lamb Abhey Pearmain, and Blenheim Orange. I have found that any of these succeed on the very stocks which the fruit mentioned had failed on. Therefore, I think this is sufficient to prove that it is not always stock or soil that is at fault; secondly, with reference to the action of frosts on the badly-ripened wood. I have noticed this frequently, but I do not think that this affects the general health of this tree. I have invariably noticed that after these "frost-bitten" growths have been carefully pruned back below the cankered parts they have made good progress the following year. Thirdly, I do not think that dressing the cankered parts will cure them. Is there not a slight confusion between canker and "American Blight" here? Fourthly, with regard to the splendid Ribston Pippin, I think it should be grown as a standard or on its own roots, and then I think it will succeed fairly well, particularly in the latter way. No variety with which I am acquainted dislikes the knife more than the Ribston. "H." says that canker has been cured when caused by rubbing or other agencies than "soil influences." I will not call this canker. "Canker is a disease," and such cases as rubbing or frating from careless staking are simply wounds, the result of accident, and can be cured by simply paring the wounds and dressing as recommended by "H." Now we come to "soil influences." I at once say that I believe this has more to do with canker than all other causes put together, and of the various influences which the soil has on the trees a badly-drained and sour subsoil must claim my first attention. I have frequently seen young, vigorous trees planted without any preparation of the soil, and they have started off at express speed, but, alas! only to be checked so soon as their roots touch the sour subsoil. I have also lifted these trees myself when the canker has set in on nearly every branch of the trees, replanted them in properly-prepared sites, and they have recovered the following year; but let it be understood these cases were

taken in time—they were not delayed till the branches were nearly eaten off. Again, poor, gravelly soil will, I am aware, produce canker, and here, again, my advice is: frequently lift your trees, and add fresh soil for their roots to strike into at once, also never fail to top-dress, even twice a year if possible on such light soils, and I venture to say that canker will give very little trouble except in those notorious varieties above mentioned. With regard to the "artificial manure remedy" for canker, I have not the slightest faith in it. I cannot believe that where canker is caused through the roots striking down into an uncegenial sub-soil, that a few dressings of sulphate of iron, superphosphate of lime or potash, &c., will restore a tree to good health, but I believe that if, in such cases, the trees were lifted, and in the course of the following summer a couple of surface-dressings of one or all of the above-mentioned manures given (provided the soil did not previously contain them), that satisfactory results would issue. The advice given by "H." so to frequently relifting young trees is excellent. This I have proved over and over again. Only during the past autumn I lifted a couple dozen young Apple-trees which were planted the year previous. I shall expect to see these trees thickly studded with fruit-buds next autumn. T. ARNOLD.

3141.—Paradise Apple-stocks.—The Paradise stocks are best raised from layers. A few old stools will throw an annual supply, but they can be purchased from any of the large fruit-tree growers. Sometimes the fibrous-rooted plants are selected from a whole batch of seedlings and used as Paradise-stocks, but are not so good as plants from layers. Crab-stocks are usually raised from seeds.—E. H.

3284.—Pear Louise Bonne of Jersey.—This is a very hardy and free-bearing Pear, and will succeed wherever Pears can be grown. A medium soil, neither very heavy nor very light, suits Pears best.—E. H.

I have seen this Pear, when visiting gardens in northern Yorkshire, succeed well, and it will grow in deep, loamy soil satisfactorily. It is a handsome Pear in shape and colour, and exceedingly popular, but its flavour is not first-rate; but it is one of the great market Pears, usually fetching a good price.—C. T.

THE KITCHEN GARDEN.

VEGETABLE MARROWS.

VEGETABLE MARROWS should be eaten young—say when about one-fourth or one-sixth their natural size. Cut in this state, and boiled quickly until quite tender in plenty of water, carefully strained, and served with melted butter, they are second to no vegetable that comes to table, not even excepting Green Peas or Asparagus. Early cutting, careful cooking, and serving are the chief points to which attention should be paid; but there are others, one of the principal being rapid growth. Crew Vegetable Marrows quickly, and they are almost sure to be good; grow them slowly, and you will find them often tough and bitter. Hence the soil or place in which they are grown can hardly be too rich for them. Not but what they do fairly well in any good garden soil, but the richer it is the better. On a rubbish-heap, for instance, Vegetable Marrows grow with wonderful vigour, and fruit abundantly. It is also a capital plant for filling any space, nook, or corner, covering dead fences or walls, scrambling over outbuildings, or growing in any out-of-the-way or rubbishy place. Vegetable Marrows should be sown in April under glass. A temperature of 55 degs. or 60 degs. will soon cause their seeds to vegetate. As soon as the plants form a rough leaf pot them off singly in 6-inch pots, and return them to a frame until re-established. The plants may then be gradually inured to the open air, and finally planted out in their fruiting places about the end of May. It is of no use putting them out earlier, as they are tender and easily injured by frost. When they make a good start in their new quarters the shoots may be stopped to make each throw out from six to eight leading shoots or stems. These may be led off in different directions to form the plant, and it is seldom that any more stopping or attention will be necessary. After the plants reach a considerable size or age a Marrow will be produced under each leaf, and if the fruits be cut young and none be left to ripen seeds, the plants will go on bearing until arrested by frost in October. If planted on rich manure

or manure-heaps the plants will need no water; but if on poor, thin, or sandy soil, they should be plentifully watered with clean or menure-water, and must not on any account be allowed to flag, else mildew will follow on the heels of the check, and the plants and produce alike be destroyed. A yet simpler way for those who have no glass and are content to wait a little longer for their Marrows, is to plant the seeds in the ground at once—about the beginning of May. A hand-light, or bell-glass, or pot placed over them may bring them up all the sooner; but they will come up without any such aids to germination and make good progress, and the plants will yield a good crop throughout the late summer and autumnal months. As regards varieties, there is the New and Improved Custard, which is much liked by some; others consider it too rich and marrow-like to be pleasant eating. The flavour is distinct and peculiar, and it needs but little imagination to suggest the flavour of custards. Moore's Vegetable Cream has a rich, mild, sweet flavour, as the name suggests; and Hibberd's Prolific is a capital sort. But there are few or no Vegetable Marrows really superior to the Old White (here figured), and Green-striped, if these be grown rapidly and gathered young. D.

3244.—Making an Asparagus-bed.—If the old-fashioned bed system is adopted the ground is marked out in beds with 2-foot alleys between. But before the beds are set out the whole of the ground should be heavily manured and trenched as deep so it will bear without bringing any bad soil to the top. A 5-foot bed will take three rows of plants, and a bed 3 feet wide will be furnished with two rows of plants.

Vegetable Marrow "Old White."

The modern system consists in trenching the full depth and heavily manuring. The ground is marked out in lines 3 feet apart. Trenches are then formed 6 inches deep and wide enough to spread the roots out straight. Plant the roots in April, just as the growth is coming away, and cover the crowns 1½ inches deep with rich compost. I generally use the charred refuse from the rubbish-yard, mixed with old Mushroom-beds, well broken up. This is the best and most economical way of growing Asparagus. There should be no cutting before the fourth year, if the future is considered. The variety named Conover's Colossal is the best. It is too late to put in Strawberries to fruit this year, unless there are strong plants in pots. The small plants usually planted should have any blossoms which may be produced picked off, and then there will be a full crop next year. Spring planting is better than waiting and losing a season. For general work it would be difficult to find three better Strawberries than Vicomtesse de Thury, Sir J. Paxton, and President.—E. H.

3223.—Tomatoes and Cucumbers.—This question has frequently been asked and answered in GARDENING during the last few months. The thing is possible, but it is a by no means advisable and always an unsatisfactory arrangement. Cucumbers delight in a constantly warm, moist, and clear atmosphere, while for Tomatoes these conditions are most unsuitable, and almost certain to induce an attack of disease. The two interests, in fact, are antagonistic, and as it is far better and more profitable in every way to grow one thing well than two or more badly, I strongly advise you to undertake one or other of these subjects rather than both. Can you not grow the Cucumbers in a hot-house? If I had to grow the two together I should plant the Tomatoes in the

idea of the house, training the stems over the roof, and grow the Cucumbers in a central bed over a mild hot-bed, covering them loosely with any spare frame-lights or old window-sashes. The light shade of the Tomatoes would not harm the Cucumbers, and the former could be freely ventilated, while a moderately close and moist atmosphere could be maintained about the latter. A much better plan, however, would be to fix a partition across the house and grow one subject in each of the divisions.—B. C. R.

TURNIPI-ROOTED CELERY.

THIS, which is also known as Celeriac, though seldom met with, is a very excellent and useful vegetable, while the culture is much more simple than that of the ordinary kind. It can scarcely be termed a substitute for the latter, as the uses are somewhat different; but it provides the table with an entirely novel and, at the same time, unusually well-flavoured and wholesome dish. With a very heavy clay soil to deal with, I find a good deal of difficulty in getting the ordinary Celery earthed up properly, so have taken to grow principally the Turnip-rooted kind, and find it not only easy of culture and to succeed well, but it is also greatly appreciated. The seed should be sown at once, in the same way as that of ordinary Celery. My plan is to sow in a well-drained box of light, rich soil and place it on a warm greenhouse shelf; but in a mild hot-bed it germinates somewhat more quickly; in any case, the soil must be kept constantly moist. Prick the seedlings off as soon as they can be well handled into other and rather deeper boxes, or into a bed of rich soil in a frame, and when sufficiently advanced harden them off and plant out in June on the level and

in well-manured beds, at 12 inches apart in rows 18 inches asunder. All the subsequent treatment necessary is to keep the ground clean, and with an occasional soaking of liquid-manure, sewage, or a solution of nitrate of soda in dry weather, they cannot fail to make fine roots.

B. C. R.

3203.—Seed Potatoes.—I presume you mean early Potatoes for garden culture. If so, get your seed cut at once, and placed when dry on a thin layer of sand, either in shallow boxes or on the ground in some sheltered place where no rain can touch them. Cover them thinly over with sand—or fine mould if sand is not handy—when sprouted; in a week or ten days (if in a warm place) plant out in drills on a fine day, about 9 inches or 10 inches deep, and from 15 inches to 18 inches apart—the drills should be at least 2 feet apart from centre to centre. Your third question is rather "Irish." How can the tops "show above ground" if you do not cover them with earth? Of course cover with earth, and when tops are from 3 inches to 4 inches above ground earth them up again to almost cover. This is the mode I follow year after year, and have always been very successful. The Potatoes should be planted on a nice dressing of half leaves (decomposed) and half well-rotted farmyard manure.—PADDY.

3230.—Cauliflower and Broccoli.—It is possible to have a succession all the year round if the weather would permit of it. But this it will not do in most districts. I have had no Broccoli since before Christmas, it being all killed by the frost, spring Broccoli included. Sow Early London Cauliflower in September, and plant out in handlights in October. Sow a little seed of Veitch's Early Forcing in February in a hot-bed, and another sowing in March of the

same. Sow Early London with Veitch's Autumn Giant in April, and this will continue the supply of Cauliflower until October, when the Self-protecting Autumn Broccoli succeeds the Autumn Giant Cauliflowers. Snow's Snoprb Winter White succeeds the Autumn Self-protecting Broccoli. I grew "Model" Leamington, and Ledsham's Latest of All, which continue the supply until the Cauliflowers which have been protected in hand-lights during the winter come in. Near London and in other cold districts the attempt to continue the supply all the year is often frustrated by frost, which kills the winter end spring Broccoli. — J. D. E.

It is quite possible to have a succession of these the whole year unless the plants are killed off in a severe winter. Cauliflowers may be out from June to November, or later. I have had Veitch's Autumn Giant sown outside in spring and planted in June up to Christmas and after, protected from frost. Veitch's Self-protecting Autumn Broccoli is very valuable planted in June and again in July; they will be in season from November till January or later, according to the season. Snow's Winter, sown in April, will follow Veitch's, and, if protected by moving to cold-houses or pits, they will last some time. Early Penzance, Cooling's Matchless, Leamington, Late Queen, and Cattell's Eclipse will continue the supply till the Cauliflowers come in in June. Sow Broccoli in April, and the late sorts, Queen and Eclipse, in May. Sow Early Cauliflowers in August and again in heat under glass in February, and sow Walcheren in April and May, and Veitch's Giant in April for late summer and autumn. — E. H.

3226. — **Auricula seed.** — I should sow Auricula seed in February if it was not sown when it ripened in July. Most of the Auricula growers save a little seed, and they sow it as soon as it is ripe, and it vegetates in a hand-light or garden frame; but the seed-pen or flower-pot in which the seed has been sown should not be exposed to the sun. A portion of the seed will vegetate in two or three weeks, but it is rather curious that most of it will lie dormant in the ground until early in February, when the young plants freely appear in a greenhouse or pit. As soon as the first leaf beyond the seed-leaves appear, the young plants may be pricked out, say a dozen, in a small sixty-sized flower-pot. The soil should be light for these very small plants, say about one part loam to one part finely-sifted leaf-mould, and a good sprinkling of clean white sand. The plants must be repotted and grown on in frames during the summer. They will grow to a flowering size during the season. — J. D. E.

It is a common thing to sow Auricula seed in the early spring, but this is by no means the best time, as the seed does not benefit by being kept out of the ground too long, nor does it care for artificial heat, but as you have the necessary appliances you may sow now, sowing the same thinly in shallow pans or boxes, properly drained, and filled with light soil. You must not get disappointed if all the seed does not germinate at all, as, under these conditions, it is slow to start, and as the seedlings appear they must be taken out carefully and pricked off into other boxes. Keep the pots of seed, however, in the frame, and the seedlings will come up very irregularly, taking care to keep the soil moderately moist. The wisest plan is to sow as soon as the seed is ripe, and they will make good plants to put out in the following spring. The best time to sow is as soon as the seed is ripe. Auriculas require partial shade and shelter from cold, cutting winds. Ordinary soil will suffice, but it must not be stagnant during the winter months. Nothing, of course, beats good loam, but one need not despair if that is not obtainable. When once a stock has been got, it is very easy to increase the plants by division of the roots, and the best time to do this is in early autumn, as then they have time to become established before winter. It is not necessary to divide often, but certainly about once in three years, as after that time the tufts or clumps get ragged, eventually dying away. You will derive much pleasure from raising seedlings, as good varieties may be expected if you sow good seed. Try and keep in stock the rich, self-coloured flowers, rejecting those of washed-out

hues, as these are by no means effective. Those varieties of a rich ruby red are very distinct and striking. — C. T.

Sow now in equal parts of loam and leaf-mould, with a little sand added, especially in the compost for covering. The seeds will do very well in the greenhouse or in a cold frame. When large enough to handle prick out in a shady border outside. — E. H.

WORK UNDER GLASS.

At this period of the year, when work out-of-doors is frequently at a standstill owing to the variation of our fickle climate, everything that can be done under glass in readiness for the coming busy season should be pushed on, for if left until the sun is shining and vegetation active outside, there is great danger lest it may have to be put off altogether. I always try to get the following jobs well advanced during bad weather—viz., washing and cleaning the inside of glass-houses, and the plants as well, and taking each house separately, I remove at least half the pot-plants to another house to make room for washing the rafters, glass, and walls, giving them a good scrubbing with warm soap-suds, and finishing off with clean water, and as soon as the walls are dry they receive a good thick coat of lime-wash, which stops up all holes in which insects might congregate, and makes the atmosphere of the house sweet and healthy, for plants certainly thrive best in cleanly houses. Then I take every plant separately, scrub the pots, clean the surface-soil, and sponge the leaves, using Gishnat compound, which destroys all thrips, red-spider, or mealy-bug that may escape being cleaned right off by the sponging. The plants are then rearranged, and another house taken in hand. Creepers and climbers need special attention in cleaning, and while vegetation is somewhat dormant is a good time to get them pruned and cleaned.

VINES also need considerable care, for if that dread scourge, the mealy-bug, gets established on them the crop of Grapes will be spoilt. Houses containing bedding-plants need frequent attention as regards clearing off all the dead or decaying foliage, every vestige of which should be removed, for leaves soon turn mouldy and, dropping on the shoots, cause them to decay as well. The surface-soil should be lightly stirred, and the shelves brushed down; but bedding "Geraniums" should be kept fairly dry at this dull time of year. Repotting plants is not advisable until the days have increased in length and clear heat is stronger than at present, except in the case of plants that are being potted up from open ground for early flowering, such as Spiræas, Deutzias, and other deciduous plants. Seed-sowing, even in cold houses, can be proceeded with, as Astors, Stocks, Zinnias, and many of the most useful summer plants can be considerably advanced by sowing the seeds in boxes of light soil, and setting them in the south front of glass-houses, as they come on very sturdily, and where heat is available Blue Lobelias, Petunias, Verbenas, and other more tender plant-seeds can be sown. A hot-bed should be got ready for striking cuttings and raising seedlings, as directly the sun begins to shine, even before frost is gone, plants make rapid progress under glass, and unless one gets the young seedlings well advanced by May, a good deal of the summer is lost. Get soils ready for potting; flower-pots should be scrubbed, and sticks and labels prepared for use. Chrysothemum-cuttings should be taken off as fast as they become large enough. They strike well in a cold frame. J. G., *Hants.*

BIRDS.

SINGING BIRDS.

THE SKYLARK.—In the early spring, if the weather be mild and open, the lhythmic song of the Skylark may be heard as it soars spirally upward in the sunshine. It is a permanent resident in this country, over which it is generally distributed. On the approach of winter Larks collect from all quarters into large flocks, when they seek sheltered situations, visiting Turnip, fallow fields, and Wheat lands. Towards spring the flocks separate and spread in pairs over the country. The ordinary flight of the Skylark is easy and undulating, and on the ground it walks and runs with great facility. It has two broods in the season. The first brood

is generally ready to leave the nest in June, the second in August. The nest is always built upon the ground in a little hollow or depression amidst corn or herbage, and is constructed of vegetable stalks and lined with fine, dry Grasses, in which is deposited four or five grey and brown freckled eggs. Young Larks should be fed upon a paste made of bread and milk, with a little Poppy or Rape-seed mixed, but the natural diet of ants' eggs is best. The yellow tinge of the plumage distinguishes the young males from the females. They begin to practise their usual song before they are quite fledged, and easily acquire the notes of other birds. Fresh captured Larks should at first be put into store cages having wooden bars, and fed on Hemp-seed, Oats, and Poppy-seed, with meal-worms. But the ordinary food may consist of Barley-meal, bread-crumbs, crushed Oats, lean meat, worms, flies, and other insects, and they must always be supplied with a fresh turf of Grass or Clover, with clean sand to dust themselves in. With care and attention this fine songster will live many years in confinement.

THE WOODLARK.—The notes of the Woodlark, although less varied than those of the Skylark, are richer, more melodious, and flute-like. It generally utters its strain upon the wing, and whilst describing large circles in the air. The Woodlark is by no means a generally diffused species in this island, but appears to be principally confined to the southern and midland counties, frequenting uncultivated fields and Cornlands bordered by woodlands. It is about two-thirds the size of the Skylark, which it closely resembles in colour of its plumage and general markings; though it perches on trees, it builds on the ground, making its nest under the cover of some low bush or tuft of herbage. The nest is composed of dried Grasses, lined with fine materials, and the eggs, which are four or five in number, are of a reddish or yellowish-white, inclining to brown, with spots and speckles, and occasionally a few very lines of rusty brown or dark-reddish grey. Young Woodlarks should be fed upon ants' eggs and bread-crumbs soaked in milk. Newly-caught birds of this species should be put into a store-cage and fed upon ground Hemp and Poppy-seed, with ants' eggs and meal-worms. A little powdered chalk given now and then is good for them, and they should always have a good supply of fine, clean sand, and also a moist fresh turf. The Woodlark is much prized as a cage-bird, but it is necessary to bestow much care upon it to keep it in good health.

THE TITLARK.—The Titlark, or Meadow Pipit, is very common in this country, where it remains all the year, chiefly frequenting damp meadows, moors, and pasturelands. Its plumage is of an olive tinge, and the spots on its breast are remarkably distinct, and extend far down the lower part of the body. It is not a very good songster, but is very docile, and soon acquires the notes of other songsters, those of the Canary more especially, and is a very amusing bird in confinement, being remarkably neat and clean in its habits. It builds early in the season, its nest being composed of dried Grasses and root-fibres, and lined with hair. The eggs are four or five in number, of a brownish-white, spotted and freckled with purplish-grey or reddish-brown. The nest is always built upon the ground, often on a grassy bank, and is generally well concealed, in which the Cuckoo sometimes deposits her single egg. Young Titlarks should be fed upon bread soaked in milk, mixed with Poppy-seed and ants' eggs. Great numbers of Titlarks resort to Oak stubbles in autumn and are then captured in clap-nets. This bird does not dust its plumage, but sprinkles it with water taken up in the beak. It should be fed upon the same food as the Skylark. S. S. G.

HOUSE & WINDOW GARDENING.

FOLIAGE PLANTS FOR A PROPAGATOR. II.

SOME of the most fascinating foliage plants for the table are Grevilles robusta (the Silky Oak of Australia) and the equally graceful Acacia lophantha, though this last has the fault—a serious one in the case of a plant for a late dinner-table—of closing up its leaves at sundown, just as the Sensitive-plant, which it much resembles, shuts up at a touch. Both these little trees are easily raised from seed in the steady heat of a propagator, and are best sown one or two seeds in a very small pot, which can be sunk to the rim in Cocos-nut-fibre. They should be repotted when about 3 inches high (giving them a little leaf-mould with spent soil and sand) into 3-inch or 4-inch pots, and put back into the propagator until they are again well established, when they may be gradually hardened off and inured to the open air in summer. The Fern-like foliage of the Grevillee is most effective on the dinner-table, and it stands well in the dry air of a sitting-room, but it will not bear Tobacco-smoke, a very small dose of nicotine being fatal to it. Small pots (with plenty of soft-water, in a clear, thin state, given once or twice a week) will grow good-sized specimens of both these plants. Canna Indica (the Indian Shot) is a very interesting seedling to raise in a propagator. The hard little hullets of seeds need soaking in rather warm, but not too hot, water for twenty-four hours before they are put in, the cup in which they are soaked being placed on a warm mantelshelf or on the pipes of a conservatory. The newer varieties, with large flowers and rather more dwarf foliage, are perhaps the best worth growing, though the brilliant carmine blooms of some of the older dark-leaved Cannas can scarcely be surpassed. Cannas grow rapidly; when once the tropical little scabths spring up from the soil they grow like magic if given plenty of warmth and moisture, flowering the same autumn, though not so profusely as the following year. They are perfect for balcony or verandah decoration throughout the summer, only needing to be lifted into shelter at the end of September, where they will gradually lose their leaves during winter, and should be repotted in rich soil with good-sized pots as soon as they start in spring.

I. L. R.

Plants in rooms.—It is usual to find in the question columns of GARDENING complaints concerning plants in rooms, their debility, and gradual decline in health. Very often the fault is in bad potting or careless watering, but more especially neglect of proper sponging of the foliage. Those who have plants in rooms, such as Aralias, Aspidistras, Felms, and other comparatively hard-leaved things should take care in a ways sponge the foliage frequently with tepid water to remove dust or other impurities from the surface. It is foolish to think that a plant can live when encased in dirt; it cannot

breathe, so to speak, and the result is a slow death. Ferns and those plants that cannot well be sponged should be syringed when necessary, to keep the foliage fresh and healthy.—T. C.

3206.—Ornamenting a parapet.—Unless you had them especially made you could not get seed-pans deep enough for your purpose, as, whatever you use as a substitute for vases, the vessels should hold sufficient soil to sustain the plants put in them. It is not only a question of soil, but of watering also; the smaller the body of the soil the more often it will want watering. A friend of mine grows his Tomatoes in huckets which have contained meringues, which he obtains from grocers. These huckets or tubs would, I think, suit you admirably, as you can paint them any colour you like; but no doubt the colour should be the same as that of the parapet. With regard to the most suitable plants, the aspect is not of the best, and against the growth of tender plants. Two tiers might be occupied with good hardy Fuchsias, and two with green-leaved Zonal Pelargoniums. I would also try Tuberosa Begonias in the most sunny position; Yellow Calceolarias will also do if the position is not too windy. If these plants are beyond your convenience you may sow such annual flowers as Nasturtium, Mignonette, Hawkweed, Convolvulus, and Eschscholtzia. Place the tube in a sunny position at once, and sow the seed, and about the second week in June they may be taken to the parapet.—J. C. C.

It is not very easy to advise you. Very deep pans may not be suitable; but the situation is, unfortunately, unless, therefore you are debarred from planting Ivy-leaved Pelargoniums, which will not bloom without sun. You might plant the Creeping Jenny and its golden-leaved variety, which will hide the pans, and plant Ferns, small-leaved Ivies, or fine-foliated things for the summer. Of course, you can get a good effect by putting in flowering-plants in pots and changing them when the flowers are over; but this will entail considerable expense and labour. I wish I could help you further, but without sun one cannot do much in the way of flowers.—C. T.

3275.—Flowers for a hall in winter.—Pot up very strong plants of the Yellow Winter Jasmine and Laurastines now, and keep them growing in a sunny position all summer, encouraging the growth by liberal treatment and the use of liquid stimulants. Strong old clumps of Christmas Roses may also be potted now, as they flower better if established in pots than if lifted from the ground in autumn, although the latter plan does very well when lifted annually, and taken back to the shady border, the soil being made rich with old leaf-mould, and the surface also mulched down with it. One of the best plants for a hall in winter is the hardy Fan Palm (Chamerope exelans); but the plants must have attained some size to possess much decorative value, though with care afterwards they will last in condition a long time, probably years. Retinospora plumosa and R. p. aurea are very useful for potting up for the corridors and the hall in winter, and they are cheap. Good bushes of Periwinkles, Skimmia japonica, the berry-bearing Aucuba,

and Euonymus in variety, are all more or less useful.—E. H.

The only way to manage the Yellow Jasmine will be to grow it in a large—11-inch or 12 inch—pot during the summer, plunged in ashes in a warm and sunny spot. Myrtles are easily grown in large pots or tubs, and Christmas Roses also. Both must be exposed outside during the summer, and well supplied with water and liquid-manure. The Golden Variegated Euonymus, Arelia Sieboldi, and Aspidistra lurida var. are often subjects suitable for this purpose.—B. C. R.

3276.—Puddling a pond.—The clay should be from 6 inches to 9 inches in thickness, and the method of making it is merely to beat and pound the clay well together until it is of the consistency of patty. The man who has to puddle the pond takes a lump of clay up in his arms and dashes it against the side of the pond, and continues to do so, dashing one lump against another until it is of the desired thickness. The clay is made smooth on the surface as the work proceeds. I had two small ponds done in this way ten years ago, and they answer very well now.—J. D. E.

I have known two or three amateur gardeners attempt to puddle a pond, but they have always failed. The fact of the matter is, it is a dirty, messy job, and requires greater care and more labour than a stranger to the work would imagine. In the first place, you must make the bottom of the pond quite firm with hard ramming before you attempt to put down any clay. Before and while using the rammer you must remove all stones that are anywhere near the surface, and if the soil is at all dry give it a soaking of water the last thing at night, and well ram it again in the morning. After this a depth of 4 inches of clay may be spread over the bottom and well rammed, so as to beat it into a united mass, finishing with a smooth surface. After this another layer of clay 6 inches thick must be laid down. This time the clay must be specially prepared by divesting it of all small stones and other hard lumps, then get a large flag-stone or some other solid substance to act as a platform on which to work up the clay. With all the materials in readiness and a bucket of water close at hand, the clay must be worked up on the platform in convenient lumps, the same way as a baker kneads his bread, until the mass is moistened through and worked into a proper condition to unite with that already laid down. After being beaten with a wooden mallet and the surface made smooth, there is no doubt but it will hold water, and last for a number of years. As the work is completed the surface must be prevented from cracking by being kept damp until the water is let into the pond, and that should be directly the puddling is finished. Of course, the work can be done without handling the clay in the way I have suggested, but it would not be done so well.—J. C. C.

3277.—Sowing seeds broadcast in a London garden.—Common, common or "Pot" Marigolds (Calceolias), Mignonette, Convolvulmaria, Scarlet Foxglove, Indian Pink, Virginian Stocks, dwarf Tropaeolum (Nasturtium), and a few Ranunculus.—B. C. R.

GARDEN WORK.

Conservatory.

Chorosemas which have passed their best may be pruned back to encourage new growth for blooming early in autumn. When fairly broke in report, if larger pots are necessary, and when the plants have reached specimen size they will not thrive annual repotting. If the drainage is right. Perfect drainage is the most important matter in connection with the culture of hard-wooded plants. If the drainage ever gets blocked the plant will soon show signs of it in its sickly appearance, and a sickly hard-wooded plant may as well be thrown out, for it is never likely to be of much use afterwards, and in these days, when plants can be so easily propagated, it is a question if it is any use keeping a sickly plant at all. A sickly plant may be useful occasionally to point a moral, or to teach a lesson, but when that object has been attained the sooner it is cast out the better. One rarely meets with a collection of Boronia now, beautiful though they are. The reason for this is probably because this is not a waiting age. Any plant which requires several years to make into a specimen is not regarded favourably, and perhaps there may be another reason why this class of plants is not often met with now. They will not do well under the treatment usually given to soft-wooded plants. Give hard-wooded plants a boost to themselves, and grow a fairly representative collection, and there will always be something in blossom to admire, and even when they are in bloom the growth of the plants has an interest apart from the blossoms. Adenandra fragrans is useful when not in blossom for the fragrance of its foliage in button-hole and other bouquet work. Among sweet-scented flowers Boronia inaequalis is worthy of a place in the conservatory. Some day there will be a run upon these old favourites again, and our greenhouses will be all the richer in effect for the change. This is a good season for repotting anything which requires more root space. But the usual time for repotting anything in the nature of a specimen is immediately after the flowering season, and the new growth is coming freely away. When plants approach the flowering stage it is not wise to repot, as the chances are the growth will be discontinued. But liquid-manure may always be used to help forward an over-loaded specimen whose roots are unduly cramped after a small pot. Climbers should be gone over frequently now, and the young shoots thinned and trained in. Use the syringe on the mornings of fine days, but keep the water off specimens in flower so much as possible. It will be very difficult to keep Chloranthus from green fly now, especially in a warm house. Tobacco-powder I have found useful, and fumigation of Tobacco may have to be resorted to in some cases; but caution is necessary in fumigating a mixed collection of plants, some of which, perhaps, will suffer from over-dosage. Zonal Pelargonium for summer flowering may be exhibited into larger pots, using rough turfy soil, slightly enriched with very old manure, adding also some artificial to each barrowful of soil. Pot firmly.

Stove.

Achilensis not yet started should now be brought into heat, and the soil moistened. Some growers shake out the bulbs and start in new compost composed chiefly of peat and leaf-mould, made porous with sand. The pots or pans are always well drained, and a few rough pieces of turfy loam is an advantage in the bottom of the pot, to carry the drainage. The roots will find it when the plants are flowering, and make in some cases require something a little stronger. Last pot is used now for the class of plants than was the case formerly, and more old turf and leaf-mould. The Hoys, or Wax-flowers, are a very interesting class of plants. H. carnea may be grown in a warm greenhouse, if kept dry, through the winter, and it forms its flowers better after the rest than when kept in the stove all winter. Every possible effort should be made before the plants come into flower to get rid of mealy-bug. This is not the kind of plant I should recommend for a greenhouse variety, for the reason that it is next to impossible to keep altogether clear of this pest. Hoys have a very charming plant for a pan or basket. It has always been considered rather a misfit thing to do, the roots so soon suffering from the least stagnation in the soil. The pan should be one-third filled with drainage, and the plant potted in rough peat and chopped Sphagnum, kept open with small lumps of charcoal or coarse sand. Under careful culture it is a charming thing, and the flowers last a considerable time. Must be shaded from hot sunshine, and never permitted to suffer from either too much or too little water in the soil.

Unheated Greenhouse.

The Chrysanthemum must be a source of strength to this house in the autumn, and well on into the winter if the weather should be mild. Those who do not require large, fat blooms may yet take cuttings, or, rather, they may with a knife detach rooted plants from the base of the healthiest and best of those of last year, and these, if potted singly, will soon make progress, and in due time can be removed to the open air for the summer, and if their wants are well attended to there will be plenty of plants good enough for ordinary decorative purposes or to supply cut bloom. Tuberous Begonias will soon move now, even though kept cool, for the season is close at hand when all plants having life will feel the impulse of the increasing temperature. The best soil for Begonias is old, rotten turf, one half, a little fibry peat, and the remainder leaf-mould, the whole to be made fairly porous with sand and broken charcoal. A compost as prepared will not easily get accident and unwholesome for the roots, and this is the chief thing to keep in mind in all plant culture. First look to the drainage, and then secure a compost which contains plenty of fibre, and blend it reasonably with sand and fine charcoal, so that when the fibre in the soil decays it cannot hold too much moisture.

Ferns under Glass.

The plants now are full of growth, and those which have been repotted are now feeling the benefits of the change. It is just possible that there may be a few of

those troublesome green-disea on some of the young, tender fronds. To attempt to deal with these by fumigation would probably lead to injury from the heat of the smoke, and therefore the best way to form fumigation is out of the question. Soft-soap, one ounce to the gallon, with about a wineglassful of paraffin-oil to two gallons of the soapy water, will, if applied through the syringe, clear off most of the insects, though it is probably a second syringing within a couple of days will be necessary to complete the cure. Large specimens should be tilted on one side, so that the mixture may not run into the soil.

Cold Frames.

No one has too many frames, or too much glass, if it is in a cheap, portable form. Some of the uses to which frames may be put now is to thin out some of the hardiest things from the greenhouses. If well protected at night bedding "Geraniums," well established in pots, will be quite safe in cold frames. Asters and Stocks may be sown now without bottom-heat, although a little warmth will be a decided advantage, and frames may be put to a profitable use in bringing onward all kinds of early vegetables and salads.

Window Gardening.

Liquid-manure in weak states may be given to Pelargoniums and other plants which are in a potting condition. Spurgees see very useful window and room plants, and if well supplied with water they are very lasting. The pots may stand in saucers containing water, and a teaspoonful of artificial manure may be placed in the water occasionally. Repot Bearbeugh Lilies if very much pot-bound, but not otherwise. Liquid-manure may be given during growth, and again in September, when, the flower-spikes are showing up. Fill baskets with Ivy-leaved Pelargonium.

Outdoor Garden.

Roses may be pruned now, especially the early districts, where the plants are growing freely. It is best to cut the dormant buds where possible, and I need not say that the cuts should be short and clean. Thin out the heads of standards by the removal of all weak shoots, as if crowded plants the blossoms must be small. After pruning fork in the mulch and leave the surface open for the air to penetrate. A close, much-trampled soil requires opening up a little at this season. Our Roses will be mulched again when the hot weather comes, but for the present, at any rate, the air will be let into the land to sweeten and purify the roots. Go over the rookery and carefully remove dead foliage and stems and then tread with suitable material to encourage growth. Peat and leaf-mould, with a little coarse sand and bits of sand or limestone, for certain plants. Evergreens will move with safety now, but the buds of deciduous things are moving rapidly, and though plants moved now might not die, they will be better left as they are till the autumn. Shrubs should be looked over and dead wood taken out. Straggling branches should also be shortened. This pruning should be done generally. Cut close back Ivy on hillings. Ivy may be planted with artificial fertilizers—this is better than deluging the soil with liquid manure. Those are well enough in a way, but their random use often injures the colour of the Grape; but when the Vines are nourished with proper compost, mixed with the old turf, the result is always satisfactory. In thinning Peaches do not overload, especially if any part of the crop will be sent to market. For some one can do so one like in the matter of thinning much or little, but for small Peaches are of no use. Keep the shoots thin and tied down as they grow. Start early Melons in hot-beds, or in hot-water-heated houses or pits, and sow more seeds of the best varieties for succession. New plantations of Strawberries may be made now, but they should not be allowed to bear any fruit, unless the plants are very strong from pots. Finish planting fruit-trees for the season. It is, of course, very late for the work, and could not be done unless there are urgent reasons for planting now. Grafting may be done as soon as the sap is in vigorous motion. Fresh batches of Strawberries should be brought indoors after fortnightly intervals. Now that we have earlier varieties for outdoor planting there need not be much keeping back of pot-planting.

Fruit Garden.

Muscate Vines, just breaking, must be delubbed by the removal of all weakly shoots. Muscate always throw many more shoots than will be required, and it frequently appears that in the case of old Vines the shoots at the beginning are weak, but by disabusing with a free hand the improvement is soon perceptible. Support pot Vines liberally now. Where possible surround the pots with rich turfy compost. I have seen the pots encircled with wire-netting, and the stuffed full of old turf and manure when further encircled with artificial fertilizers—this is better than deluging the soil with liquid manure. Those are well enough in a way, but their random use often injures the colour of the Grape; but when the Vines are nourished with proper compost, mixed with the old turf, the result is always satisfactory. In thinning Peaches do not overload, especially if any part of the crop will be sent to market. For some one can do so one like in the matter of thinning much or little, but for small Peaches are of no use. Keep the shoots thin and tied down as they grow. Start early Melons in hot-beds, or in hot-water-heated houses or pits, and sow more seeds of the best varieties for succession. New plantations of Strawberries may be made now, but they should not be allowed to bear any fruit, unless the plants are very strong from pots. Finish planting fruit-trees for the season. It is, of course, very late for the work, and could not be done unless there are urgent reasons for planting now. Grafting may be done as soon as the sap is in vigorous motion. Fresh batches of Strawberries should be brought indoors after fortnightly intervals. Now that we have earlier varieties for outdoor planting there need not be much keeping back of pot-planting.

Vegetable Garden.

A good supply of forced Asparagus, Seakale, and Mushrooms at this season is most important, and will cover any deficiencies in other directions. But though the winter has been rather severe, the damage done to the green crops has not been so far as I have seen, very serious. Broccoli, though possibly small, will be plentiful, and other kinds of greens fairly supplied. Mushroom-beds may be made up in the pots and saw-wood shavings of any kind. I have had good profits made by filling trenches with warm manure, treading it down firmly edging the beds (and the larger they are the better) with rough boards, and covering with waterproof cloth or wooden shutters. A good breadth of early Nantes Horn Carrot may be sown now to succeed the early bed on the main border. Young Carrots are very acceptable at all seasons, and by sowing in succession, first under glass and afterwards on the warm border, following with a further bed in the open air, and finishing off with a sowing in July on the warm border, to be protected in shelter, will bridge round the year. Everything should be done now to secure a good supply of good Lettuce. Glass will be necessary for this object, to be early covered

ont. Gentle hot-beds made of leaves and stable-manure are very suitable for the growth of Lettuce and salads of all kinds at this season. The Paris Market Cabbage (which is very early), and beds of vegetation of any size, may be planted 8 inches apart, or if sown in the frame they may be thinned out to the distance named, and the thinnings pricked out in another frame, or on the warm border outside. French Beans will do best now planted in pots or frames on beds of manure that will insure a temperature of 60 degs. or so. French Beans in vinery or Peach-houses are apt to encourage red-spider, and if the insect makes its appearance the Beans should be cleared out at once. See that sufficient Celery has been sown for the main crop, and prepare a bed for sowing outside for late use. When Celery is sown in the frame in April, though the plants will not grow so large, they will keep in condition much longer, and will suffer less from stress of weather, and will not run to seed so soon. E. HONDAY.

Work in the Town Garden.

Camellias, as soon as the flowers are over, should be placed in a moderately warm house or pit, and kept close and moist, both at the root and overhead, with light shade from hot sun, when this gains a little more power. Where there is no second structure the plants should be kept in the closest and warmest end of the greenhouse, and frequently syringed overhead. This treatment, though not absolutely necessary, causes the plants to make vigorous growth, and set an abundance of buds in good time. Any straggling branches may be cut back, and under the conditions indicated they will quickly break into fresh growth. Repotting also may be performed now with the best results, but in the case of plants that have been pruned to any extent better defer this until the fresh growth is a couple of inches in length. Similae treatment may be accorded to Aesculus of the Indian section, and if repotting is not judged advisable let the plants have some weak liquid-manure or soot-water once a week while the fresh growth is being made. Take care to pick off any seed-pods that may have been formed. The Persian Cyclamens are in great beauty now, and as the flowers fade should be placed in a warm greenhouse, and kept in order to mature the foliage perfectly, but still keep the plants regularly moist at the root. About the middle of April they may be removed to a cold frame to be hardened off, and early in June place them on a bed in a shady spot for the summer, but never allowing the roots to want for water. Plants from seed sown now in heat, and pushed on briefly, will probably flower to some extent next winter. I have sown the first week in April and then had flowers by the following January, but the best plants seen obtained by sowing in July or August, wintering the seedlings in boxes or small pots in a warm greenhouse, and potting them on during the following summer until the 5-inch or 8-inch size is reached, when they will bloom abundantly the second winter. Old Chinese Primulas that began blooming early, and are to be kept over for another winter, should now have all the flowers and buds picked off and be hardened off, and finally stood outside in a shady place in June, in the same manner as recommended for Cyclamens. Keep them fairly moist, repot in July or August, and if healthy they will bloom profusely again next winter. Sow Primula obconica in border water, and P. sinensis for early flowering in the double kinds are extremely pretty and useful. Sow hardy annuals in the open ground, and a bed or two of Phlox Drummondii, Asters, and Salpiglossia under glass. Hardy trees and shrubs may be planted at any time now. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from March 18th to March 25th.

Grafted several large Apple-trees which bore indifferent fruit. The grafted were strong pieces of two-year-old wood. For large limbs old wood is best, as when cut in with the axe the sap can be drawn off freely, and there is not the same danger of being blown out with the wind when the top gets heavy. Planted Potatoes. The land works well, and a good many have been got. One of the best late Potatoes is, I think, Imperator. The crop is always heavy, there are very few small ones, and for the three years I have grown this variety there has been no disease worth mentioning, and last, but not least, the quality has been invariably good—far superior to the Magnum from the same soil, although the latter is generally free from disease. Planted several rows of Duke of Albany Red; this and Walker's Perfection Bees are, I think, two of the best Peas for supplying a family. Planted out Seakale roots in rows 15 inches apart and 12 inches apart in the rows. Tied down young wood in early Peach-beds. Watered and Alexander did not set so well as the other varieties in the same house, but the late blossoms did fairly well, and there is plenty for a good crop. Sowed hardy annuals in beds and borders; these are used chiefly to fill the between herbaceous plants. Shifted on Tomatoes to fill unheated houses. Ham Green Peas are the best for the purpose, but I believe in unheated houses for Tomatoes, but the houses are only now in course of erection, and the heating will be delayed till the autumn, and as the position is a sunny one I have no doubt the crop will be a good one. Dis-lubbed Vines in late house. Fire-heat will be used regularly till the summer weather comes, so I prefer to do a good deal of the work at this end of the season, rather than pot it all off till the autumn. Grafting Colman requires as much heat as Muscates to ripen them properly, and will pay as well for it. Potted off bedding plants in variety. Shifted the strongest Chrysanthemums into 5-inch pots. They are kept on the fire till the coming week with keeping out frost. Put in cuttings of the large-flowered Yellow Irish Daisy. I had a good-sized patch of this in the reserve garden last summer, and the empty cut bloom was Immense. Sowed Stocks, Asters, Phlox Drummondii, Double Zinnias, and Salpiglossia; the last named form a very pretty mass, distinct from most other things. Planted another house of Cucumbers, the variety being Locke's Perfection, and set out a small house with Melon in pots. The pots are of large size, and are plunged in the bottom-heat bed. Melons must have bottom-heat if they are to be good in round. Flashed training seedling of the best Melons. These have gone out of cultivation in some private gardens, but they are very useful, both for outlying and for making groups in the conservatory

* In cold or northern districts the operations referred to under "Garden Work" may be done from two days to a fortnight later than is here indicated, with equally good results.

when well grown, and as soon as they get shabby they are cut down, the cuttings put in, and for some time they do not require much space or much attention. Pricked off seedling Gloxinias and Begonias. Shifted on a few young half-specimen Ferns. Several old plants have been thrown out to make room, and when Ferns get old they are best on the rubbish-heap, as they are not worth keeping. Cleared out exhausted Asparagus roots from the hot-bed where forced. Stirred up the bed a little, and planted it with French Beans. Finished planting out Carnations that had been wintered in pots in cold frame. Planted Gladiolus. Disbudded Pigs under glass, and pinched the shoots left at the fifth leaf. Shifted on young Palms.

INDOOR PLANTS.

PELARGONIUMS AS WALL PLANTS.

It is not so generally known as it should be that Pelargoniums are very excellent greenhouse wall plants (see illustration). Many of the strong-growing Zonal kinds are remarkably well adapted for this purpose, and so are the Ivy-leaved ones. The old early-flowering varieties of the large-flowered section, Gauntlet and albummultiflorum, do well on walls, and amateurs who may wish to have a little variety in their greenhouse would do well to bear in mind the value of the strong-growing Pelargoniums as wall plants. B.

POINSETTIA PULCHERRIMA.

This is one of the brightest and most attractive plants we have for decoration during the duller months of the year. It would be difficult to find anything to surpass in brightness the beautiful scarlet bracts or leaves which surround the terminal clusters of rather inconspicuous flowers. Although, strictly speaking, a stove plant, when properly treated it is a fine subject for conservatory or house decoration. It has now been in cultivation upwards of fifty years, yet its culture does not seem to be too well understood at the present time. Like many other plants from the tropical regions, this is often kept too close and warm during the summer and autumn. Being naturally of rapid growth and inclined to grow tall, under close treatment, especially when shaded as well, the plants run up until they are too high for ordinary uses. Various modes of treatment are recommended by different growers, and no doubt when properly carried out each may be equally successful. If treated as follows there will be little difficulty in growing short sturdy plants, which will keep their foliage and produce fine heads of the beautiful scarlet bracts. In the first place, the strongest and best ripened plants should be selected for stock. After being well dried off, these may be cut back to where the wood is quite firm. They may then be stored away under the stage in a warm-house, laying the pots on their sides, so that no moisture gets to the roots, and remain in this condition until they begin to start into growth in the spring. I like to keep them dormant as late as possible, but as soon as they begin to start they should be stood upon the stage and a little moisture given. Water should be used very sparingly until the roots have started sufficiently to take it up. After they have well started a little manure may be given to induce vigorous growth, good strong cuttings being the first step towards success.

CUTTINGS put in in June or July will make the best plants. The first batch, however, will be ready much earlier than this, and it is advisable to take the cuttings off as soon as they have made sufficient growth, especially where the stock is limited. When the cuttings are taken off some dry sand should be at hand to apply to the base, which will stop the milky sap from flowing. The cuttings should be put in singly into small pots, using a light sandy compost. If everything is in readiness they can be taken off and put into the close propagating pit without getting withered. I like to delay watering for a few hours, which gives time for the base to dry up sufficiently to prevent further bleeding. If kept close and well shaded they will soon take root. They must be removed from the pit as soon as they have started, and may be gradually exposed. When well rooted they may be potted on into 5-inch pots, in which they will flower. I have seen them succeed well in verone composts. I prefer loam, leaf-mould, and well-rotted manure, with sprinkling of sharp sand, but have seen good results

when potted in the first-mentioned, and also when peat has been the chief component.

WATERING is a most important matter, either excess being equally disastrous. In growing the plants on they should have as much light as possible, and plenty of ventilation during the summer. I have seen them grown in pits with the lights off during fine weather, but I prefer to keep them under glass. When the plants are well established liquid-manure may be used freely. In the autumn, as soon as the nights get cool, a little fire-heat should be given. The temperature requires careful regulation, for although no visible harm is done by keeping a low temperature, the result will be seen later on, as when more warmth is given for the development of the bracts the green leaves will fall off. On the other hand, the plants grow very rapidly just before they begin to set their bloom, and a high temperature will result in

Zonal Pelargoniums on a wall.

tall, leggy plants. Just before the flower-heads begin to form the plants may be kept a little drier, and no manure should be used. As soon as they are well set, or the first bit of colour can be seen, more warmth may be given and liquid-manure supplied freely. I should add that those propagated early may have the tops taken off. These make good cuttings, and the plants will make two or three shoots, and if potted on into larger pots they will make equally fine heads of bracts as those with single stems. The main points towards success may be summed up as follows: Strong cuttings struck late in the season, careful attention to watering, regular attention to temperature, and a light position as close to the glass as possible.

VARIETIES: There are several slight variations from the type, besides which we have the variety with creamy-white bracts, and the double form *P. pulcherrima plenissima*. This is more delicate than the normal form, but is more

worthy of cultivation on account of its coming in a little later, and when well grown it is more showy. In addition to the whorl of bracts at the base of the cluster of flowers, each flower has another whorl of smaller bracts, which are equally bright in colour and fill up the centre well. The white variety, *P. pulcherrima alba*, is rather delicate and does not form such large heads; nevertheless, it is very useful, and should be more extensively grown. Of other varieties *rosea-carminata* is distinct; the bracts are hardly so bright as those of the ordinary type; its chief recommendation is that it comes in a little earlier. Some years ago Mr. Spary, of Brighton, raised a batch of seedlings, among which were several distinct variations. These were exhibited at a meeting of the Royal Horticultural Society, but owing to their not having names, the committee did not deal with them, and Mr. Spary, who was then in failing health, did not take the matter further. I do not know if the varieties were entirely lost, but they do not appear to have been offered in the trade. I believe other growers have raised seedlings, but those above alluded to are the most distinct that I have seen. M.

The Scarborough Lily.—Now, just as they are commencing to make fresh growth, is the right time to repot plants of this deservedly favourite Vallota. Plants that have been wintered in a greenhouse from which frost has been just excluded, and watered occasionally, are now in luxuriant health, and producing quantities of young bulbets round the base of the old bulbs. It is a mistake to let these charming plants go very dry, even during the depth of winter, as they are properly evergreen, and if watered each time the soil shows signs of dryness, even during the depth of winter, will retain a quantity of foliage in quite a cool temperature. There are two ways of growing this plant, one being to give each young bulb or offshoots and all—a moderate shift every spring, when a glorious mass of flowering bulbs will be the result in three or four years' time, and the other to remove the offsets and keep the single old bulb in a pot of about 6 inches diameter. Even quite small bulbets, with two or three leaves each only, will, with good culture, become nice flowering plants in eighteen months' time. *Vallota purpurea* occasionally perfects one or more pods of seeds, and if this is sown when ripe, a number of sturdy little plants will result. The way to induce this Lily to bloom freely is to treat it generously, and ripen the growth by free exposure to sun and fresh air in July and August.—B. C. R.

Yellow-spathed Callas.—There are two very distinct Yellow Callas or Arum Lilies in cultivation, one named *C. Pentlandi* and the other *C. Elliottiana*. The spathe of the former are of a rich golden-yellow colour, large, and are very handsome, in rich contrast to the deep-green leaves. Like the common *C. ethiopicum*, that may be seen in every florist's shop, it is probably a native of South Africa, and first flowered with Mr. Robert Whyte, Pentland House, Lee. It is interesting to notice that the bulbs were given to Mr. Whyte by a friend, who expressed the conviction that one of them would prove to have yellow flowers. The flowers of such a distinct novelty was naturally looked forward to with keen interest, and one would probably have rose spathe, but, as far as I know, this decided departure has not yet revealed itself. *C. Elliottiana*, also a yellow-spathed, but quite distinct from *C. Pentlandi*, the flowers of the former being marked with white, similar as in *C. bastata*, and it has been suggested that *C. Elliottiana* is a cross between the common *Calla* and *C. hastata*. Whatever the parentage of either novelty, it is satisfactory to know that they are likely to prove good garden plants. Then here is the further anticipation of varieties with spathe of other colours. A rose variety would indeed be an acquisition.—C. T.

Spring flowering bulbs in pots.—It is strange that amateurs do not grow more the many beautiful kinds of spring flowering bulbs that may be bought very cheaply. Bulbs potted up in the autumn will give welcome bloom in the early year, and as a rule about six bulbs in each 5-inch pot will be ample. A very useful flower for this purpose is the Glory of the Snow (*Chionodoxa lucida*), which is a perfect

weed on the rockery, once it gets established, if such a charming thing can be thus described. In a pot the flowers are naturally pretty, their colour being a bright blue, the centre white, and its relative, *C. Sardeusis*, may be also thus cultivated, the flowers of which are smaller and of intense blue shade. Then one may have *Soilla bifolia*, the many bulbs of bulbous *Iris*, as *I. Bakeriana*, *I. reticulata*, *Snowdrops*, the finer kinds of *Crocuses*, and many other gems of the opening year. A greenhouse may be made bright with colour with the use of such hulks.—V. C.

3224.—**Primulas for spring.**—Presuming that the Chinese Primulas are meant, therefore to obtain a good bloom next year in the spring, the seed should be sown in May or June. The seed will not vegetate all at once, but will appear irregularly. The small seeds should be pricked out in small pots in sandy soil; loam, leaf-mould, and sand in equal proportions suite them. The seed at that time of the year will vegetate in a garden frame; but it will come up more freely in a hot-bed with a little bottom-heat. The plants should be grown in frames with a north aspect until the end of September. Any of the leading seedmen who advertise in GARDENING can supply the seed, and each of them have what they term their own strains. Not many seeds are found in a packet, and it is best to get a packet of each colour, rose or pink, deep-red (this is termed in the trade scarlet and crimson), white, and in red varieties.—J. D. E.

3224.—**Shading for a conservatory.**—The best shading is a medium scrim cloth for the purpose by horticultural sundriesmen, to run up and down with lines and pulleys. This is expensive. The cheapest and a good hind from the sun is a green powder sold under the name of "Summer Cloud." Paint the glass outside according to directions; it can easily be washed off again in the autumn.—J. D. E.

—The most suitable shade is afforded by tiffany blinds, as they can be rolled up and down according to the weather, and taken away in the autumn when no longer required. If you do not mind the extra expense roller blinds are far preferable, neater and better for the plants. They are not then in perpetual shade, so to speak; but if you think a cheaper shading would be better in your case, try some preparation, such as "Summer Cloud," or a good material for shading is made by mixing lime or whitening with milk until it is quite thin. This will be found very useful, and another good preparation is Brunswick green, dissolved to the consistency of thin paint. A dense shade is unnecessary. At one time houses devoted to Ferns had green glass, as it was thought that every ray of sunlight was hurtful. We have learnt better now.—C. T.

3280.—**Calceolarias in frames.**—I should begin hardening the plants off at once by drawing off the lights on all fine days, and giving more and more air, at nights also, unless very frosty. During such weather as we are now enjoying scarcely any protection is necessary, and if gradually inured to free exposure, by the early part of next month the frames may be removed altogether. Get them planted where they are to flower about the middle of April, as they never do so well as when planted early.—B. C. R.

—If the plants are in a position sheltered from the north and east, the frames may now be removed. I have had some hundreds of cuttings in boxes in a cold pit, and they were turned out-of-doors on the 4th of March. They will be planted out in a border much further apart than they have been in the boxes during the winter. The plants will increase in size until it is time to plant them out in the flower garden.—J. D. E.

—You may take the frames off now if you can substitute a covering of canvas or oiled calico for them till the plants get thoroughly hardened.—E. H.

3297.—**Plants for the wall of a greenhouse.**—A collection of Ivy-leaved Pelargoniums would be very effective and the flowers would be useful for cutting. The following are suitable: *Souvenir de Charles Turner*, *Madame Thibaut*, *Mignon*, *Jeanne d'Arc*, *H. Cannell*, *La Francoise*, and *Sarah Bernhard*. Plant 3 feet apart, and the wall will be covered in one season. *Clematis indivisa lobata* and *Paeonia Elizabeth Gem* will cover the roof. By the way, *Clematis*

scandens will make a pretty creeper for a greenhouse, very free in growth.—E. H.

—Camellias would be very suitable for such a position—nothing better could, in fact, be named. *Fuchsias* also might succeed fairly well, but "*Geraniums*," and *Eucalyptus* in particular, would not thrive at all well, both

French Forcing Turnip.

being essentially "sun-loving" plants. Next to Camellias, *Habrothamnus elegans*, *H. fasciculatus*, and *H. aurantiacus* would be most likely to succeed. Any of the finer kinds of *Clematis*, also *Paeonia oerolea* and *O. Constance Elliott*, would flower fairly well, but I should give the preference to *Fuchsias* and *Lapagerias* as more likely to thrive and bloom abundantly.—B. C. R.

3229.—**Cannas from seed.**—It is late now for these, February being the proper month to sow, but if the seed is got in at once in a hrek hot-bed, and the plants pushed on with plenty of heat, moisture, and nutriment, they will make fine plants and bloom well in August or September. The seed should be soaked in water at 90 degs. to 190 degs. for twenty-four hours, then sow in pans of light, rich, sandy soil, plunge in a hot-bed of 80 degs. to 90 degs., and keep moist. Pot them singly when 3 inches high, push on in a warm moist atmosphere, and repot as required. Old plants are propagated by division of the clustered crowns in spring, the pieces being potted singly and started in a gentle heat.—B. C. R.

3280.—**Greenhouse for succulent plants.**—This class is by no means particular, and will succeed in a structure of almost any kind, but by preference it should be light, sunny, and well ventilated. On the whole, I should prefer a span-roofed house in a fairly open situation, and 16 feet or 18 feet in width, with two pathways, two narrow (3 feet) stages on each side for the smaller plants, and a wider central one for the larger specimens; length anything over 25 feet. Such a house should be heated by two rows of 4-inch hot-water piping all round, but a smaller or narrower structure, especially if a lean-to might be efficiently and cheaply warmed by means of a fire, as these plants do not suffer from a dry atmosphere like most other subjects.—B. C. R.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

THE KITCHEN GARDEN.

FORCINO EARLY VEGETABLES ON HOT-BEDS.

Those who are responsible for keeping up the supply of vegetables are aware of the advantages of obtaining early those kinds which may be forwarded by forcing, and such being secured, it generally gives satisfaction to all concerned. It does not matter to what extent the usual winter kinds have been provided, such as the various Kales, Broccoli, Leeks, and the usual routine of root crops, the palate is apt to tire of these unless they can be varied by forced produce. Certainly it will depend upon the means or appliances provided whether forced produce may be secured or not, for without the ways and means, no man—let him be ever so painstaking or persevering—can be expected to cope with the difficulties which would beset his path without the aid of pits or frames, and also a certain amount of fermenting material. With these aids provided, then the forwarding of early vegetables could be carried out in a successful manner. I look upon a good supply of fermenting material as being a surer aid to secure good produce than even heated pits, unless it be with such vegetables as French Beans, or even Potatoes and Asparagus, although these two latter kinds are generally the most satisfactory when one is supplemented by the other. Fermenting material stimulates growth without unduly drying up the atmosphere, and with a body of this for bottom-heat root crops are more satisfactory in every way. Carrots, Radishes, and Potatoes and Turnips (see illustration), as root crops, are seldom found fault with for being too early, and, of course, the same may be said with French Beans, Asparagus, or even Lettuce. Rhubarb and Sea-kale can hardly come under the heading of forced vegetables in the same sense as the other varieties mentioned, for although these are forced, certainly they are different from the other kinds, so need not further be referred to.

GENTLE AND LASTING HOT-BEDS are what is needed, and this can only be provided with abundance of good stable-litter and a plentiful supply of leaves, preferably Oak or Beech, although others may be relied upon when these are not forthcoming. At the present day, now that heating by hot water and light structures may be had at a much cheaper rate than formerly, the old system of heating by fermenting material has gone out of date. Merely carting the litter from the stables and mixing a quantity of leaves with it, to be made up into a bed at once, is almost worse than nothing at all. In the first place, this would heat so violently as to be dangerous to plant any kind of vegetable for fear of its being injured by burning, and also because when once this violent heat stage has passed the bed so rapidly cools, until the heat is very quickly expended and of little use for stimulating the crop. A gentle and lasting heat is what is wanted, and this can only be secured by properly preparing the material. The litter must be well shaken out in the act of turning, the leaves also being added as the work proceeds. In the course of a day or two the mass will require turning again, and perhaps again and again until the violent heat is expended, when it will be ready for forming into beds. In my own case I have deep brick pits, and although with these linings cannot be added, yet by well preparing the material the brick walls confine the heat sufficiently to bring the crop to maturity. The heating material being confined, the heat is not blown out to the same extent as when the beds are exposed. This is the more reason why hot-beds are best formed in sheltered places out of the range of rough winds. In making the beds, well shake out the material as the work proceeds, building the sides up perpendicularly, beating them well with the back of the fork. Placing the material on in layers and trampling it down is not the best system to adopt in making a hot-bed. The depth of the beds must be gauged by the crop it is desired to plant. For instance, a depth of 3 feet will be ample for Carrots and Radishes, the same for Lettuce, and for the earliest Potatoes 4 feet, although later on 3 feet will be ample. The beds should be formed about 6 inches larger than the frames to be placed on them, and it may be necessary to place other fermenting material within the

frame to assist in bringing it up to the desired height.

ORDINARY GARDEN soil is not the best for the crops to root into, unless leaf soil and burned garden refuse or any lighter material that will assist in ensuring a genial root-run be added to it. Old potting soil, also the old material which has been utilized for Croumbers and Melons, with the addition of burned refuse, is as good as anything for the purpose, and a depth of 8 inches, or 9 inches, of this spread equally over the frame will ensure rooting space suitable for any vegetable crop. Carrots and Radishes may well have a frame or part given up to each, although the latter may well find a place in the Potato frame, being ready for use before being smothered up with the Potatoes. The evil generally is in sowing the Radish seed too thickly, as in this case one crop spoils the other, and especially the Radishes. The Potato sets being previously sprouted, these should be set out not less than 15 inches apart in drills drawn 4 inches or 5 inches in depth. Whatever crops are grown, it will greatly depend upon the management of the frames whether they turn out satisfactory or not. Allowing the soil to become so dry as to shrink from the frames is a grievous evil. Although Potatoes do not show signs of distress so quickly as Radishes, Carrots, or even Lettuce, yet the produce will be very scanty unless the soil is kept nicely moist. Radishes and Carrots would also be poor in quality and tough in texture, and the quicker they are grown the more satisfactory the crop. Keeping the frames unduly close, and perhaps forgetting about the ventilation until the temperature is raised high by sun-heat, and then suddenly giving perhaps a great amount of air, cannot but affect the crop to a serious extent. Leaving the ventilation on too long, although this may not affect the growth to a serious extent, yet by closing early so as to retain as much solar heat in the frame as consistent with safety, often makes a difference of a fortnight in the time of the crops coming to maturity, and which is to be considered when perhaps forcing against time. Covering up the frames during the night is another detail which should not be neglected, taking the precaution, however, of not covering up so early as to exclude daylight, also uncovering early enough in the morning for the same means—small points certainly, but often neglected. Coming to

LETTUCE, see what capital produce may be had by the aid of shallow and gentle hot-beds. Forcing Lettuce is resorted to a deal more than formerly, and this change was brought about on account of the Parisian market-gardeners supplying our markets with sweet and tender Lettuce, whilst in our gardens such produce was conspicuous by its absence; and, indeed, our markets are still principally provided from that source. At one time this kind of Lettuce was looked upon as only being able to be produced in France, but quite as good may be grown in this country by adopting the hot-bed system. Varieties of the Early Paris Market are the kinds used, and from plants provided by autumn sowing already under hand-lights or cloches placed rather thickly together on long and shallow hot-beds, the earliest are now ready and followed by others. Certainly light, artificially-heated structures have superseded hot-beds, and have to be resorted to where fermenting material cannot be had, but the latter is still the best for many purposes. A.

A few good Peas.—One of the most useful and productive Peas in cultivation is Duke of Edinburgh. The pods are not large, and the plant grows tall—often 7 feet or 8 feet—but it keeps on growing, flowering, and podding continuously in a way that no other Pea I know of does, affording an unbroken supply for eight or ten weeks at a stretch. Duchesse is an exceedingly handsome Pea, with unusually large straight pods and Peas of the finest quality. It is very even in growth, and a well-grown row just in perfection is quite a picture; but, unlike the former, it is soon over. Wm. Hurst is by far the best dwarf Pea we have, very productive, and seldom exceeding 15 inches in height. For succession I find the old Sunrise as good as any.—B. C. R.

3271.—Good King Henry.—This is the Chenopodium Bonus Henrious, or Goose-foot, and is sometimes used as a vegetable, being

supposed by some to be a good substitute for Asparagus, and the leaves when the plant has made some growth are used as a substitute for Spinach. The young shoots are cut as Asparagus in April and May, and when well grown are as thick as the little finger. They should be planted in a sunny position to come in early in April. The plant is a free, vigorous grower, and may be raised from seeds or plants put in some time in April. The ground should be well trenched and richly manured, and manure-water may be used during the summer months when the plants are in free growth. The plants should be set out 9 inches asunder.—J. D. E.

—This vegetable is in season as soon as the leaves are large enough to be used as Spinach, and will continue usable till the growth gets old and tough in summer. The young shoots are sometimes used like Asparagus in spring, but it is only from strong roots that such shoots can be taken without injuring the crops of Spinach-like leaves.—R. H.

3274.—Mushrooms in a frame.—Mushrooms may be grown successfully in any kind of frame made with rough boards, with a waterproof cloth or wooden shutters to cover over the top. The shutters will be better than glass, as Mushroom do not require light, and the glazed lights will make the frame too hot in summer. The site for the bed might be excavated a foot deep, as shady spots should be selected, or some place not much influenced by the sun's warmth, for the spring and summer beds. The manure should be worked into a sweet, genial condition by fermenting in a heap before making up the bed. But the manure should always during the process of fermentation be turned over before the heap gets very hot, as manure that has spent itself in heating is not adapted for Mushrooms. When the ammonia has all been driven out, as Mushroom-producing material its value has been injured. This is one of the reasons why Mushroom-beds fail. Another important matter in connection therewith is to keep the heap of manure sheltered from heavy rains; it is absolutely useless for Mushroom growing when much washed with rains or overheated. If the beds are made in a wooden frame, covered with shutters, the depth need not exceed 15 inches, and the top may be made flat. When made altogether in the open air, the beds are usually made in a ridge form, with a base of 3 feet or so, and the ridges about 2½ feet high, rounded at the top. When made in this way the whole of the surface is available for the Mushrooms, and, of course, the whole of the surface will be planted with spawn. The beds should be made quite firm, the shutters placed over, and the bed then left till the temperature is steady from 85 degs. to 90 degs., a thermometer being placed with its bulb sunk 3 inches or 4 inches in the manure to indicate the condition of the temperature. Break the spawn in pieces a couple of

the thermometer inside, put on the covers, and in six weeks the Mushrooms ought to be coming through, and a damp cover with a rosed pot with tepid water will be advantageous; but the bed will not require heavy watering till the crop of Mushrooms begins to thin off a bit, then a soaking of liquid-mannre, in which a little salt has been dissolved, will give an impetus to production.—E. H.

—You appear to have a wrong idea about the value of a frame for Mushroom culture. Its only value for this purpose is that it serves as a protection, otherwise as good Mushrooms can be grown during the summer without it, and the time is near when the beds can be made up in sheltered places in the open better than they can be made in a frame. If you have suitable manure you may make up a bed in a partially shady place, and place the frame upon it. A bed of well-prepared manure 2 feet 6 inches high will give all the heat necessary. After the spawn is inserted keep the bed in darkness; but you had better have a thermometer in the frame to indicate the temperature—if it exceeds 65 degs. ventilate it to bring it down to that figure; if it sinks lower than that put a lining of stable-manure round the bed, reaching half-way up the frame. Give the bed a gentle watering three weeks after it is spawned; but the water must be warm. In cold, windy weather cover the frame up with mats or dry long litter, or the heat will get blown out of the bed. If you have to make up the bed fully exposed to all the sun, keep the frame well covered up in bright weather.—J. C. C.

OUTDOOR PLANTS.

GOOD ANNUALS.

CLARKIAS.

It would, we think, be well if amateur gardeners would bear in mind the claims of the Clarkias as being amongst the best annuies. They are extremely showy and easy of culture. Seeds may be sown in spring or in autumn out-of-doors. When the plants are in their flowering quarters a distance of 9 inches to 12 inches apart should be allowed. Most annuals are spoiled by overcrowding. A good form of White Clarkia is here figured.

EVERLASTING PEAS.

THESE start early into growth, and anyone anxious to increase his stock should lose no time in lifting and dividing, as they push out strong underground shoots before making any show above ground. They are not only valuable plants for screens or covering arbours or wire-fences with a wealth of foliage and bloom, but they are specially adapted for cutting. Although there are several varieties of Peas of Everlasting or herbaceous habit of growth, Lathyrus latifolius is the best, for it produces large spikes of rose-coloured flowers on long, stout footstalks that are most useful during the latter part of summer, when a good many of the garden flowers are beginning to wane. It is not at all particular as to soil or situation. I plant the roots at this time of year in any bank or spare piece of soil, and stick in some good stout, rough Pea-sticks, and let the Peas ramble at will over them, and will do they repay the space they occupy. The white variety, Lathyrus latifolius albus, is a charming plant, but by no means so vigorous as the rose-coloured variety. I grow this against low walls, on which some wire-netting is fastened to train the growth to; and in preparing the site, I take out a wide trench two spits deep, and in the bottom I put about 15 inches of brick rubbish, and on this a layer of turf, and fill in with good garden soil. The plants are put in about 3 feet apart on slightly raised mounds, and when in good condition few white flowers are more useful than this one is.

J. GROOM, Gosport.

A good form of White Clarkia.

inches in diameter, and place them just under the surface about 8 inches or 9 inches apart, and then beat or press down the surface to a firm and level condition; and when it is ascertained that the spawn is working freely, cover the bed with the Damp soil one and a half inches, beating it down with the back of the spade. Leave

3188.—Culture of Pinks.—The Pink should be more grown in gardens, as it is not difficult to cultivate, and gives plenty of flowers early in summer. You will find Mrs. Sinkins one of the most useful kinds, but the flowers are unfortunately much given to splitting. They are, however, large, white, and fragrant. Then

there is the charming fringed white, called *fimbriata alba*, the common kind familiar in every cottage garden, Anne Boleyn (rose, the centre deep-crimson), Ascot (pink, the centre carmine), Lord Lyons (deep-rose), and Rose Perfection (cherry-rose). A few of the choicer show kinds comprise: Minerva, Boiard, Ethel, Modesty, Empress of India, Ernest, Henry Hooper, Duke of York, Duchess of Fife, and Louisa, James Thurston, Eurydice, R. S. Hector, Ophelia, Godfrey, Amy, and the Rector. I do not know whether they are all in cultivation, but that may be ascertained on application to a nurseryman who especially grows this class. The White Pinks, Anne Boleyn, the Clove Pink, Ascot, and Lord Lyons would make a good commencement. Pinks are not so fastidious as the Carnations, and good plants put in now will bloom in the summer, but the soil must be well prepared. The proper time to plant is quite the early autumn and in the spring. Make the plants firm, as they are sometimes loosened by frost, at the same time carefully stirring the surface of the bed, and a slight dressing of well-decayed manure will do no harm. As regards the propagation of the Pink, the best way is by pipings, which may be taken late in June, and they will strike readily in a piece of ground prepared in a shady corner, the soil made fairly rich. Cut the pipings below a joint, dibble them into the prepared soil, and place a hand-light over them. They will root well under such conditions, and even in the open in a shady corner if the soil is light, and in the event of hot weather shaded and wintered with a fine roset watering-pot, so as to make a spray, twice a day. It is not necessary, but hurtful, to drench them; merely, so to speak, syringe them. When dibbled into a wooden box, and stood over a gentle hot-bed, roots are formed very quickly, but it is not necessary to go to this expense and trouble. When rooted, plant them out in a prepared bed to get thoroughly established, and in September put them into the positions they are to occupy in the garden. During the winter season, if there are frosts, then thaws, it will be necessary to look to the plants occasionally to see that they do not get thrown out of the ground. Avoid wet, and we advise you to raise the bed a little above the ordinary level. As you are late with the planting do not delay, choosing the first fine day, and a mulching of well-decayed manure and leaf-mould will afford the plants much assistance. If you need information on growing plants for exhibition flowers, a separate article will be necessary, but I presume you only require the Pinks for ordinary garden decoration.—C. T.

The Japan Primrose.—This fine Primrose should be in every good garden. The plant makes a strong, vigorous growth, and although on its first introduction considered tender, it was soon found to be quite hardy. On the rocky, border, or where opportunity occurs in the woodland, *P. japonica* is at home, delighting in a shady position, which is also moist. The leaves, when the plants make good growth, are large, and the scapes tall, bearing the flowers in tiers, opening one after the other, and thus maintaining a display over a long season. One gets great variety in the colour. The richest is the deep-crimson kind, with a darker centre, but there are also white, salmon-rose, and various other shades. This variety in the colouring makes the plant more interesting. Seed sown in the usual way in a seed-pot, and placed in a frame, will germinate well, remembering that it sometimes remains dormant a considerable time. Those who can plant this Primrose in the woodland will be well repaid by the fine growth of the plants, the long succession of flower, and varied colours. It may also be grown in pots, but I do not care for it thus sown—soot so much as in the open.—V. C.

The Balearic Sandwort.—A charming plant for covering the faunings of stones on the rocky is the Sandwort of the Balearic Islands (*Arenaria balearica*). It covers the stones with a green carpet, spangled in the spring and summer months with a multitude of white stony flowers. When planted against the stones in fairly light soil it will in time creep over them and hide their sharp outlines. This note was prompted by a mass of it recently noticed on a bit of rockery, the position moist, and the plants was of the richest green colour, a reflecting

to look at as the Grass in the fields. It seems to dislike very hot situations, preferring moisture and moderate shade. It is a delightful thing to establish upon a wall.—V. C.

A fine Sunflower.—A very fine Sunflower, one of the best of all the perennial kinds, is *maximus*, which makes a splendid bed in the autumn months. It is well named, the plant growing over 6 feet in height, and the flowers of large size, rich yellow in colour. Although of such bold character it is neither coarse nor engagingly. A well-prepared ground is necessary, but in most gardens this Sunflower will attain fine proportions, blooming freely in the later months of the year. Autumn is most thought of as the best time to plant, but in October may, with a proper selection of plants, be made as gay almost as summer. The Helianthus are a host in themselves, and of many kinds this is of fine character.—V. C.

Garden edgings.—I have noticed lately several queries in GARDENING respecting garden edgings and substitutes for tiles. In very large gardens plants are used for edgings, and such things as the Mossy Saxifrage, Thrift, London Pride, and Stonecrops are excellent for the purpose, not being cold and hard as the common tiles one sees in gardens. A very charming edging is made of stone, over which Stonecrops and Saxifrage are permitted to grow. In country gardens the Centaurea may be encouraged as an edging, its mat-like growth adapting it well for this purpose. The Common Thrift (*Armoracia vulgaris*) is a very distinct edging and pleasing to look at all seasons, being rich-green throughout the winter, and when in bloom a mass of rose-pink colour. London Pride is another plant for edging, and if not allowed to get starved flowers freely. It is usually thought, however, that this familiar plant will stand the roughest treatment and the poorest soil; but it must have good ground to ensure satisfactory growth. In the London parks, Regent's-park in particular, the Mossy Saxifrage and London Pride are freely used, and succeed well in spite of smoke.—V. C.

3291.—**A flower-hed.**—Begonias (Tuberous) are the plants for your purpose. Procure enough one-year-old tubers (mixed colours look best, I always think) to fill the bed when planted about a foot apart. Start them in shallow boxes of sandy loam and leaf-mould in the greenhouse, pot singly when in growth, and plant out the second week in June. They will flower continually until the first frost. If you cannot do this, you must buy plants in growth. Work the hed well, and mix a moderate quantity of leaf-mould, spent Hops, or well-decayed manure with the soil.—B. C. R.

—You must wait until the foliage of the tubers has died down before you lift them, if you wish to get a good display of flowers next season. At the end of May you could plant many charming things. Tuberous Begonias would bloom throughout the summer until cut off by frosts, and the plants, if of a good strain, are very neat and the flowers bold, varied in colour, and produced above the tops of rich green leafage. They would certainly make it brilliant, and you could have as an edging some variety of Tufted Pansy as *Achillea Crant*, the colour of the flowers agreeing, of course, with the kind of Begonias used. A white-flowered variety, with an edging of light blue of Tufted Pansy is very pleasing. These you have also Zonal Pelargoniums, succulents which are very interesting in a bed, if several kinds are mixed together, Lobelias, Calceolarias, Potentillas, and various other bedders; but I should plant Tuberous Begonias, one colour for the centre, then a line of another shade agreeing with that in the middle of the bed, and an edging of Tufted Pansy. Tuberous Begonias seem less monotonous than Pelargoniums, Potentillas, etc.—C. T.

3283.—**Flowers under trees.**—Bulbs, such as Anemones, Snowdrops, Daffodils, and Wood Anemones, would do very well for early spring flowering. Primroses also and Polyanthus would be suitable, as would also *Violas* in variety, Forget-me-nots in variety. The British plant Woodruff, would be charming. One of the Everlasting Peas might be planted to train up the stems. Clematis *Flammula* might be made use of in the same way. Among annuals, *Limnanthes Douglasi* and Nasturtiums in variety would help to brighten up the

and some of the long shoots of the tall Nasturtiums might be trained up into the trees.—E. H.

—There are very few annuals that succeed to any extent in shade; but seed of Pansies sown at once in a frame will produce flowering plants by about July. Auriculas, Primroses, and Polyanthus sown now will also flower next spring, and thrive well. Other suitable subjects are Violets, Lilies of the Valley, Periwinkles, Daffodils, Hypericums (Rose of Sharon), Hespaticas, Myosotis (Forget-me-nots), and Snowdrops.—B. C. R.

—You cannot grow annuals or such things under the shade of trees, but Daffodils will do well. In market gardens this bulb is largely cultivated thus, and a charming picture is produced, as well as ample cut-bloom afforded. Lily of the Valley might be also planted, as it likes partial shade, and good clumps of it put in at once will bloom this year. You may plant Wallflowers, Forget-me-nots—and they look remarkably well under an Apple-tree—Solomon's Seal, and Spanish Squill. I like to see Daffodils, however, preferring them to anything else for such a position.—C. T.

3273.—**A hed of Begonias.**—I do not think you will be very successful in pegging these plants down, as the stems are very apt to snap off just above the bulb if pulled about. If you want nice dwarf plants have nothing to do with old bulbs, which always grow more or less tall and "leggy," but procure either quite small tubers of last year, or good forward seedlings of this season; these always make the prettiest plants to my mind.—B. C. R.

—Why not let the plants grow their own way to develop their characteristic habit and growth? The Tuberous Begonia is one of the most compact plants one can use for bedding, yet it is not general. If you get a good strain you will not be troubled with leggy stems, but the growth will be even, bushy, and the flowers produced in profusion just above, a rich and effective result. If you put out good plants as soon as all fear of frost is over, you will get a rich display of colour if a variety of colours is chosen.—C. T.

3211.—**A wind-swept garden.**—I should think you are well advised by "J. C. C." to set a double row of Elms at the north end of your garden. But with an extent of 2 acres in such a situation you will not find one break to the wind sufficient. Where there is anything in the nature of a draught the current sweeps down again very soon. You will need several screens across the garden. If you plant hedges, Hawthorn or Beech might serve the purpose, or perhaps one of Damon-trees amongst the vegetables. Yew or Box will make a more fitting screen near the lawn or flower-beds. Watted hurdles or rough wooden trellises covered with Creepers might serve and take less space. Years ago I saw a garden in a very windy part of Cheshire, near the Mersey, that was a good example of making the best of a bad site. The house stood in about an acre of ground; a leafy screen of trees enclosed the whole plot. In front of the house was a small paddock; behind, the ground was divided into little squares by deciduous hedges, at least 10 feet high. The garden was famed for its fruits, especially Pears; they grew on low trees inside the close. Original and unusual in aspect, this garden had a charm of its own. On the windiest day on that bleak coast there must have been shelter in that sequestered spot. Screens are largely used in the Scilly Isles. Without this protection it would be impossible for the inhabitants of those exposed islands to grow the Daffodils and other spring flowers that they export in such numbers.—ALL WINDS' HOUSE.

3248.—**Seeds of hardy perennials.**—The best way is to sow these in well-worked beds of sandy loam, with which has been incorporated a moderate quantity of leaf-mould. If the weather is dry, cover with mat until germination has taken place; these are better than Moss or litter. The seed may be sown either broadcast or in drills, preferably the latter, on account of the greater ease of weeding. Sandstone grit is quite unnecessary; if the soil is naturally coarse or rough, make up a fine surface with old potting- soil, road-sweepings, or the like. Some time in April is the best season to sow.—B. C. R.

FRUIT.

BEST EARLY APPLES.

ECHLINVILLE SEEDLING.

THIS Apple (here figured), as is pretty well known, grows to a prodigious size, and generally is a free bearer, and it cannot be surpassed for cooking whilst in season. It does best as a naturally-grown pyramid, with very little pruning. As a dwarf standard, with, say, a stem of 3 feet, it succeeds well. This variety is quite as profuse as the old Keswick Codlin in the formation of fruit-huds, these appearing even quite plentifully on the wood of this current season, and this on the Crab-stock, which is well suited to the variety. A.

SLOPING VINE BORDERS.

IN the majority of cases Vine borders have to be of dimensions, form, and constituents not always under the control of those who make them, but there are many blunders that might often be avoided. The prevailing idea would appear to be that they must be given a good slope from the back to the front, and, as far as outside borders are concerned, this form answers well, not because a good fall to the front helps to throw off excessive rainfall, but rather on account of a slight angle bringing the border more under the influence of all the sunshine going. Now I believe that this plan of sloping outside Vine borders may easily be overdone, while they are altogether uncalled-for and faulty when similarly constructed inside the houses. Warmth and air are undoubtedly most congenial to Vine roots, but when these conditions are made paramount, events may not prove so satisfactory as anticipated. The roots, and through them the Vines, more often than not suffer from want of moisture than of heat, and it is the sloping borders that dry up the most quickly, being also much the most difficult to re-moisten. Nor is this the only fault I have to find with this class of border. It is my firm belief they do more to promote an injuriously deep root action than is atoned for by an increase in the temperature of the soil over that of more flat or nearly level borders. The cultivator, by top-dressings of a root-enticing or root-inducing material, contrives to fill the surface of the border nearest the stems with abundance of root-fibres, only to lose many of them when their hungry points spread a short distance towards the front. A portion of them strike downward, but only a comparatively few find their way into the surface of the more shallow part of the border. Doubtless much can be, and very often is done towards keeping the fronts of borders well filled with roots by means of liberal top-dressings of soil and manure, mulchings of leaves and straw manure also being applied; but these alone are not sufficient, and plenty of water must be supplied during a moderately dry time, or otherwise not many healthy root-fibres will be found. When we come to discuss the state of sloping

INSIDE BORDERS, the objection is even more pronounced against this method of forming them. In not a few instances the gardener has scarcely any choice in the matter, or is under that impression, the initial mistake having been made by the designer of the structure. Too often the foundations are not got out deep enough to admit of a good depth, or, say, from 30 inches to 3 feet below the door-sill or level of pathways being obtained, and raising either the one or the other being almost out of the question, a sloping border is the almost sure consequence. The very illustrations of vineries given by some of the leading horticultural builders, showing inside borders, make these sloping abruptly to the pathway on both sides, no matter how narrow one or both of the widths may be, and unless the gardener has had some previous unsatisfactory experience in the matter, that is

the inevitable style of border that will be made. To make matters worse, the hot-water pipes are also fixed very low, and not unfrequently only a short distance from where the stems of the Vines will be located, the evil being aggravated accordingly. In the latter case not only is there every prospect of the narrowest portion of the border becoming much too dry, but that at the deepest side will also be robbed of much moisture by the hot-water pipes. Plenty of cuses are met with where the return-pipes are actually buried in the soil or mulchings, rendering this "as dry as a bone," and destroying all active roots that come into contact with it. Once borders thus situated become dry, it is next to impossible to re-moisten them by ordinary measures, and if the roots leave such unsuitable quarters and force their way through brick or stone walls into the open ground, this is nothing to be wondered at. In this neighbourhood there are two vineries with inside borders necessarily made sloping to the pathway, but, fortunately, the gardener in charge fully realised the danger of allowing them to become quite dry, and the quantity of water applied during

three or four years. Many of the old roots found might well be cut back 4 feet or more, while those better furnished with fibres or presenting a healthier appearance generally, few of which probably will be found within 4 feet of the boundary wall, might be preserved. A width of from 4 feet to 6 feet having been cleared, the latter figure being by no means extreme, especially in the case of very old or much exhausted borders, add a fresh width of 2 feet or rather more of good, fresh, loamy compost. This must be kept up together by means of a wall of turves, the next best thing being a loose brick wall, which will be found quite strong enough for the purpose. A perfectly flat outside border is neither necessary nor desirable: but it ought to be made very nearly so, the front wall being built up to a good height accordingly. The new portion of border should be sufficient for two years, and when the time has arrived for adding another width the front of the turf wall may be shaved off with a spade, and the new soil be packed firmly against the old loam. The latter being well stocked with roots it will not be long before the new soil is also taken possession of, the consequence being an improvement in the Vine's health. It may not always be convenient or possible for a new width of border to be added, good loam, for instance, being very scarce in many gardens. In this case, the slope of a border may be gradually lessened by simply lightly top-dressing the deepest part, and more heavily so the front, with fairly rich loamy compost. This should attract many roots, and in any case render it a much easier matter to well moisten the border whenever necessary. Doubtless the autumn, or before the leaves are changing colour, is the best time for interfering with the roots of Vines; but there is no good reason why it should not be done any time before top-growth is far advanced this spring.

TOP-DRESSING may be applied with advantage at almost any time of the year. Inside borders may be levelled in much the same way, turf walls answering even better under glass than they do in the open. I have seen them bristling with great white roots, and the borders, when raised well above the level of the walks, and kept well supplied with water, must derive great benefit by the extra exposures to heat, air—moist or otherwise. Better by far be content with a comparatively narrow square border, say, half the width of the house, than have a much wider sloping border that cannot so readily and surely be made congenial to the roots. Every drop of water applied to a level border must find its way downwards or to where it is most needed; whereas, there is very much waste connected with those that are sloping, especially if, as before hinted, they are allowed to become the least bit dry before the attempt is made to properly moisten them. Square or level borders are, therefore, the most economical, and there is no mistaking which proves the best for the Vines to root into. W.

OUR READERS' ILLUSTRATIONS: Apple "Echlinville Seedling." Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. W. Cooper, Manton, Frome, Somersetshire.

the growing season was almost startling. They are well watered, sometimes once and frequently twice in one week, and if only there had been more head-room allowed, no fault could be found with the weight and appearance of the crops produced during the past six years. But what if water had been scarce—and it is far from being plentiful in the majority of gardens? Or, again, what would happen if a fresh man, who did not consider the risks to be run, or, in other words, either did not believe in the necessity for or neglected to give so much water as previously, took charge of the place? Failure inevitable and complete would be the result of either a scarcity of water or neglect to apply it in abundance, always provided the Vines were unable to send their roots out into a moister root-run on the other side of the foundation walls. Having pointed out

THE EVILS attending the construction of sloping borders, it is only right that I should suggest a way out of the difficulty. This is simple enough as far as outside borders are concerned. In not a few cases it would be a very judicious proceeding to considerably reduce the width of these borders, at any rate for some

3292. — An Apple-tree for a small garden.—It is not wise to encourage the growth of two kinds on one tree, especially such a weak growing sort as Irish Peach. No variety that I know of in the whole range of the kitchen section would match this dessert Apple in point of constitution, as it is naturally a weakly growing sort. Much better results would be obtained by restricting the whole of the tree to one kind. If an extra early Apple is wanted for the dessert Irish Peach is good, but a much superior Apple is Cox's Orange Pippin in every respect. The best early Apple for cooking purposes is Lord Grosvenor, and for late use Lane's Prince Albert, both remarkably free bearers.—S. P.

A northern garden.—For the encouragement of those who live in bleak districts in the north, I should like to say what flowers I have sown (Feb. 23rd) out in my garden, which two years ago was simply a field. Four kinds of

Christmas Roses, Aconites, the large Snowdrop, the Pink and White Winter Heath, the large Hepatica angustata, Pink and White Mezerion, Bulboodium verna, and Saxifraga Boreociana major. Besides these the flowers of little alpine Rhododendron are almost expanded, and are only waiting for a little sunshine, as are also the rosy blossoms of Saxifraga oppositifolia, the Pink Doge-tooth Violet, the ordinary Violet, the delicious sweet-scented Winter Heliotrope (Tusseilago fragrans), and the bold and yellow flowers of the Doroicum, and the Pink Megasea, and one of the Andromedas. Among the flowers out, I forgot to mention the Winter Jasmine, which has been in great beauty since November. I live on the Harrogate side of Leeds, and in a very cold, wind-swept district, but I do all I can by hedges and walls to protect and make cosy nooks for my dear flowers. I have also several large raised mounds, with a few large sandstone blocks half buried in the rotted turf of which they are formed, in which smaller things that could not do with the cold damp of clay in winter live and flourish exceedingly. I think I have said enough to show that the coldest garden may be brightened by a few flowers, even in the blakest season of the year, if their owners will have it so, and will take ordinary care in planting and sheltering them. —NORTHERNER.

TREES AND SHRUBS.

3281.—**Planting Rhododendrons.**—If the loam is suitable in which the Rhododendron are planted it is a good plan to mix with it some sand, and if leaf-mould can be obtained this is better than manure; but a little manure, well-decayed, is excellent for Rhododendrons, and may be used whether they are planted in loam or peat. All kinds of loam do not suit Rhododendrons, and if it contains lime they will not thrive in it.—J. D. E.

—There is a great deal of support in good peaty soil, owing to its being in reality formed of decayed growths; hence, Rhododendrons do not need much artificial support when growing in such soil. In loamy soil, a little soot keeps it dry and more open, and also aids these plants very much. Well-decayed stable-manure, especially such light material as comes from an old and dry Cucumber or Melon-bed, is also very beneficial when planting Rhododendrons upon loamy soil.—P. U.

—If the loam is suitable for Rhododendrons they will do better without manure than with it, but unless your loam has been tried and found suitable, you nor any one else can say if they will take kindly to it. The composition of loam, however, differs so widely that it is just possible that which you have may answer. I am well acquainted with the behaviour of Rhododendrons when growing in a loamy soil, which they like, and my experience is that they make stronger growth and produce larger trusses of flowers than those cultivated in peat, and I feel certain that manure mixed with the soil would be a positive injury, unless it was decayed almost into a powder. Thoroughly rotten manure spread on the surface they do not object to—ca a matter of fact, when it gets well decayed the roots will come to the surface for it. As you evidently have to make your soil, I advise you to excavate the bed rather deep, if the position is naturally well drained, and in doing so allow a depth of 2 feet of soil, with the surface just under the surrounding level; this will give you space above for giving a top-dressing every second year, without injuriously raising the bed to the drying influence of sun and air.—J. C. C.

—Good loam will grow these shrubs well. Peat is better, but on loamy ground I have seen splendid plants. If, therefore, your soil is of this character, you need trouble no further, as you may expect excellent growth. When planted give a good watering in dry weather during the summer, as Rhododendrons are apt to suffer if neglected in this respect. The finest examples in the country are grown on the fine Surrey loam.—C. T.

—Unless the loam is naturally poor, the plants will do just as well without manure as with, and whatever of this kind is used must be thoroughly decayed and sweet. If, however, leaf-mould is procurable, it may be freely used, both mixed with the soil and applied as a mulch after planting, with the greatest benefit.—B. C. R.

—Over the red sandstone found (in the) throughout the country from One-hire to Worcester, the Rhododendron grows very well in the red loam, but I always found when I lived among them that a top-dressing of old leaf-mould, or very old cow-manure, had a beneficial effect upon the size of the blossoms and the vigour of the plants.—E. H.

3272.—**Watering Ivy.**—It is too early yet to expect Ivy to make much growth. It will grow fast enough presently. In the way of a stimulant the best thing is nitrate of soda, 1 oz. to the gallon of water. Dissolve a handful of soot in each canful as well, and soak the ground around the plant thoroughly with the liquid about once a month during the summer. If in a town the soot may be omitted.—B. C. R.

—Liquid-manure, or a top-dressing of manurial compost, spread over the roots as a mulch will encourage the plants to make stronger growth. Old leaf-mould or very old manure mixed with loamy soil, used as mulch, will be a great help. Drainage from a manure-heap, or guano dissolved in water at the rate of half an ounce to the gallon, may be used.—E. H.

—Ivies do not care for a good deal of water; all they need is a fairly moist soil. But if your position is unusually dry an occasional copious watering will benefit them. As you do not give the name of your variety, it is impossible to judge if it is naturally a strong grower or not. Although Ivies will thrive in very poor soil, they prefer a rich and open compost, and, minus these, applications of manure-water will benefit them a great deal. The drainings from a stable, freely diluted, guano at the rate of 1 oz. to a gallon of water—in fact, almost any liquid stimulant will answer your purpose. There is, however, a vast difference between the habit and strength of Ivies, and it is a pity you give no guide as to your variety.—P. U.

—There is nothing much one can do except to leave the plants alone. It is quite unnecessary to dose Ivies with a liquid-manure or artificial preparations. The plants cannot be expected to make great headway in two years, but if they were planted carefully and have since been given ordinary cultivation they will succeed well. Many complain that Ivies make such poor growth at the commencement, but the truth is that any kind of planting is thought proper. They are simply stuck in the ground and left to themselves. Always put in good plants, and during the first two summers or so water them liberally in hot weather. Perhaps you have got some tender kinds or small-leaved varieties that will not grow so strongly and quickly, or such sorts as Emerald Green, canariensis, and Ragnersia. If the position is very hot, and the soil unusually dry, as it is sometimes against a house, the growth of the plants would not be very rapid. In that case give plenty of water in the summer months. Ivies like moisture and shade.—C. T.

3283.—**Lilac-bushes in a London garden.**—"Selanum" cannot do more than he has done in order to induce these trees to flower in his position. They need a fair amount of light and sunshine to mature the bloom-buds, otherwise flowers of any merit cannot result. As your plants are growing healthily, I would not manure them any more for a couple of seasons, when perhaps a less vigorous growth may mature more thoroughly and set itself flower-buds better.—P. U.

—Remove the encumbers about the base of the shrubs, and provide the plants with an open, sunny spot, where they can get plenty of light and air. These are the chief things to consider, as the shrub will grow in almost any kind of material, but not make progress if cramped for room or deprived of proper air or sunshine. If your plants are healthy, and the spot is not shady and enclosed, there is no reason why they should not grow well. But doubtless it is the position they are in that is the cause of the mischief. In Battersea-park, for instance, the glorious masses of Lilacs are the chief charm of the place when in flower, but they get the two essential conditions, light and air. Lilacs are good town shrubs when thus provided, or rather, one ought to say, excellent to plant in suburban gardens. Not many miles from the City I know several splendid specimens, given no attention from year to year, yet flowering profusely each season. They are, however, in full light and get an abundance of air.—C. T.

—These should be moderately manured and pruned annually, cutting out the suckers and young shoots from the base, but they never flower so freely in town as in the country. The Persian Lilac is the most prolific variety.—B. C. R.

3282.—**Gold and Silver Ivies.**—It is interesting to get so many queries in GARDENING about Ivies, as they are very charming in their variegated forms. As regards cultivation, Ivies do not really want any, the great point being in the first place, especially of the variegated kinds, to get good plants, so that they will grow away at once, and cover the wall quickly. Also during the first summer, until they get thoroughly established, give liberal watering occasionally. Unfortunately, some of the best variegated Ivies are very tender. Madeiraensis variegata, which has bold, well-marked leaves, gets much injured in the winter if the weather is severe for any length of time, and Algeriensis variegata is also apt to suffer. If, therefore, the situation in which you are going to plant them is at all cold, exclude these kinds. The following will, however, prove suitable, and the variegation is well marked. You must try and get them true to name, as, from my experience, varieties are called by different names in the various nurseries. Amongst the small-leaved varieties choose those named, and of each variety a short description is given. Marginata major is very useful, the leaves medium in size, and with a bold margin of yellowish-white colour; the growth quick. Some of the variegated Ivies are not well coloured. Palæata aurea, for instance, is variegated in name only. Latifolia maculata has large leaves, marbled with a whitish colour; and a suitable kind is also H. rhombos variegata. Marginata robusta has large foliage, margined with silver. Those with small, silvery leaves of value are minor marmorata, which are well variegated, Folia argentea, margined with silver, and H. japonica. As regards the golden-leaved kinds, a good selection would be of the larger-leaved varieties, Folia aurea, the foliage medium in size, and the variegation decided, and it is of quick growth. Aurco maculata is useful, the leaves variegated with a yellowish colour. While of the smaller-leaved varieties may be chosen marginata aurea, the foliage with a margin of gold; and you may also select, if you need bushy varieties, very pleasing in a bed, the silver and golden variegated varieties of arborescens. A very good Ivy for colour is stropurpurea; its leaves are of a rich, bronzy-chocolate colour, abundant, and pleasing to look at in the winter months. All the kinds named are fairly robust, some more so than others; but it is the green-leaved kinds that are the stronger of the two. This is a good time to plant.—C. T.

3225.—**Grafting Rhododendrons.**—There could not be a better time than the present for this operation, provided your stocks are in a fit condition. Seedlings of the common ponticum variety are usually used as stocks upon which to work the choicer kinds. The method known as "whip-grafting" is the one most generally practised. It consists of paring away a portion of the graft and a corresponding part of the stock, fitting the two together and binding them firmly. In the trade it is usual to pot the stocks and work them in February. The shelter of a close pit or under late Vines causes the sap to work early, and, being free from drying winds, a union is effected more securely than if grown out of doors.—P. U.

3288.—**Belladonna Lilies.**—These plants do not flower well in the open ground, unless they are planted in a good position, and in deep, suitable soil—loam, leaf-mould, and sand. They should also be planted in the front of a hot-house, facing the south. They succeed admirably treated this way in Kew Gardens. The bulbs may be planted in June, and if they are to be grown in pots I would also plant them in that month; singly in pots would be the best way, using good sandy loam. They will only flower well if they are encouraged to make good growth, for it is during the period of growth that the flowers are formed for next year, and when the growth has been made the plants must have a period of rest. The Belladonna Lily should be pnt in a glass frame in the hot sun when resting. Donu Herbert writes in the "Ameryllidaceæ," page 276, that he planted bulbs of this Ameryllie at 2 feet distance from the front wall of a greenhouse and stove, and in favourable seasons he has had 200 flower-stems rise in September in thick patches. He adds: "I have seen City stems in close contact. A

rich and even strong and manured soil is agreeable to them, and a south wall promotes the dying of the roots in summer. They very rarely flower with me in the middle of the garden."—J. D. E.

I do not advise "Black Bees" to attempt growing these Lillies in pots or tubs unless she has plenty of room in her greenhouse, as they require a good deal of space through the winter, when room under glass is most valuable, as they begin forming their leaves early in the autumn, and develop them during the winter when the conditions are favourable. If they are unfavourable they make only a poor attempt to grow, and then they do not flower. If you make the attempt to grow them in pots take up the bulbs at the end of July, and provide them with plenty of root room and a strong, but not overrich, soil. I advise you to try the effect of giving them the protection of a cold frame during the winter, so as to protect the leaves from injury. Take up the bulbs at the time I have suggested, and plant them close to a wall facing south, so that they can have fresh soil, and have a frame made about 18 inches wide, with a movable light to put over them during the winter—a long, hot-bottomed box with glass on the top would do. You will never get any flowers until the leaves

blooming as they do in large clusters; Banksiana, Félicité Perpetuelle, and Leopoldine d'Orleans are three of the best light kinds, with Flora and Princess Marie of the darker or rose-coloured varieties. These, like the Hybrid Bourbons, require merely to have the weakest wood thinned out, leaving all the strongest or as much as can be used. Of the Hybrid Perpetual class the following are a good half-dozen: Olory of Cheshunt (one of the best of all the red sorts), Princess Lonica Victoria (very free in the autumn and a good climber), Boule de Neige (the best of the whites), Climbing Pride of Waltham (pink), Climbing Edouard Morron (rose colour), and Climbing Victor Verdier (bright-rose). Of the Hybrid Teas, Cheshunt Hybrid (carmine), and Reine Marie Henriette (deeper carmine), are two of the best, both growing freely. The Climbing Tea Roses of the Dijon class are amongst the best of all. Oloire de Dijon must still be included; to it should be added Mme. Borod (of a deeper shade), Kaiserin Friedrich (a beautiful newer kind, very vigorous), Mme. Eugène Verdier (chamois-yellow), Waltham Climber No. 3 (bright-crimson), and Belle Lyonnaise or Bouquet d'Or (the former a pale kind, the latter a deep salmon-yellow). To these must be added Céline Forestier (pale-yellow), Rév-

higher and larger in the back row, and instead of having more room they receive considerably less. Boxes can always be pitched at any angle after they are placed on the staging bench. For six Roses I use a box 18 inches square. One does not want his set of twelve or six to appear as a continuation of his neighbour's, and a little extra space prevents this. Keep the tubes well towards the centre of the boxes, forming three rows deep, whether it be for a set of six or twelve, four in a row, and two in a row respectively. As regards fixing the tubes, much must depend upon their make. I know some who simply about half-fill up their box with short Grass or litter, and then insert the tubes, afterwards filling in between with the freshest Moss they can obtain. By-the-way, fresh Moss helps the appearance of the blooms wonderfully. My own tubes are made with a square foot, and over the corners of these I tack a thin lath, which keeps them firm and in their places during travelling. I afterwards fill in between them the same as already described. This is the most secure and simple way. If boards be used and a thin layer of Moss placed over this, there is the difficulty of making the same stick occur, there not being sufficient depth of Moss to hold them.—P. U.

3203.—Climbing Roses in a lean-to house.—As you want the flowers for cutting Cheshunt Hybrid appears to be a suitable Rose for your purpose, as it is a vigorous grower, but it is unfortunately very subject to mildew when grown under glass. General Jacqueminot would be my choice for such a position, as it gives you the colour you want. Then there is Reine Marie Henriette (Red Glory) which is a capital grower, and if it gets plenty of light it flowers more or less all the summer.—J. C. C.

I should much prefer Reine Marie Henriette to Cheshunt Hybrid. It comes darker, of better shape, and keeps its colour better than the Rose you suggest. I also consider it a much freer bloomer. Yes, you can grow Chrysanthemums and a few Camellias in the same house very well.—P. U.

3298.—Roses for the garden.—"Rosy's" experience of the varieties named is very much the same as my own. Silver Queen makes good growth, but opens much best during a dry summer. So, too, do the other more double varieties mentioned: Marie Rady, Comtesse de Serenye, and Ferdinand de Lesseps. The former of these must not be grown too generally if good blooms are to result. I find it does much better when cultivated upon rather poor ground. Reynolds Hole grows well with me, but does not flower very freely. The following are twelve good Roses, and I have placed the six dark ones first: Charles Lefevre, General Jacqueminot, Victor Hugo, Abel Carriero, Prince Arthur, and Madame V. Verdier; Mrs. J. Laing, Margaret Dickson, Boule de Neige, Misse Hassard, Elie Morel, and La France.—P. U.

Some of the Roses you mention are not habitually bad doors—Marie Rady and Comtesse de Serenye, for instance—the others, however, are of doubtful character, and I advise you to discard them. The following dark Roses are sweet-scented and fairly good growers: Prince Camille de Rohan and E. Y. Teas (crimson), Eclair and Lady Helen Stuart (pink and other shades of colour included), Mr. J. Brownlow, Duchess of Albany, Mrs. J. Laing, Rosy Morn, Heinrich Schultheis, La France, Magna Charta, Marie L. Pernet, and Elizabeth Vigener.—J. C. C.

I am pleased to know that sweet-scented Roses are asked for. Everything, however, nowadays seems to point to the exhibition, and the finest show blooms are often, unfortunately, either practically scentless or very slightly fragrant. One of the most fragrant Roses I know of recent raising is Angustine Ouinoissean, a beautiful garden Rose, popularly known as the White La France through its deliciously sweet flower, which are produced freely, and white, touched with soft rose. It is a good autumn bloomer, and should be in every garden, whether large or small. Another exceptionally fragrant Rose is the Hybrid Comte d'Espresmel, one of the R. rugosa section, the flowers semi-double, but so fragrant that a few will scent a large room. It is one of the most fragrant Roses I know, and makes a fine spreading bush. Then you can have Oloire de Dijon, La France, the Hybrid Bourbon variety, Mrs. Paul (the flowers large, white, with the petals margined with a rosy tint, and of the fine form), the well-known Souvenir de la Malmaison, Caroline d'Arden (a

Roses on arches.

develop properly, and if you live in the north of England you had better give up their culture altogether.—J. C. C.

ROSES.

ROSES FOR ARCHES AND PILLARS.

ROSES which possess a vigorous constitution and annually make long growths for flowering the following year are the most desirable varieties. Selections may be made both for early flowering and for more continuous bloom through the season. Of the first-named class are the Hybrid Bourbons, some of which are the finest Roses grown when treated properly. My own plan is to lay in all the strong wood and thin out the weakest every spring; on no account should the vigorous shoots be pruned, or fresh wood will only ensue. These strong shoots should not be left upright, but be trained over or downwards; hence they are better suited for arches. Thus treated they will bloom most profusely, yielding an abundant supply of flowers before the Hybrid Perpetuals are in many cases showing colour. Of the Hybrid Bourbons, the four finest are Blaire No. 2 (blush-pink), Charles Lawson (vivid-rose), Coupe d'Hébé (deep-pink), and Vivid (crimson). Hybrid China Mme. Plantier, a pure-white, is a delicately beautiful old-fashioned Rose, and very free-flowering. The Bourbant Roses should not escape notice; they are of the hardiest, and will thrive where many only fail or drag out a miserable existence. Amadis, one of the earliest, gracilis (bright-red), and elegans (crimson) are all good sorts. The Evergreen Roses (R. sempervirens) are among the very best for roses

d'Or (buff), the well-known W. A. Riobardson, and Lamarque (pure-white, should have a warm spot) from the Noisette class. For poor or cold soils the selection should chiefly be made from the Hybrid Bourbons, the Evergreen Rose, and the hardiest of the Teas and Noisettes, as Gloire de Dijon and Révo d'Or. In such positions manure should be used freely, that from the farmyard being preferable; draining should also receive attention, being most essential. Moderate pruning the first season is advisable to form a good face. The ground for these Roses should be deeply dug or tronched, adding fresh soil as well as manure if the ground is not up to the mark. A mulching after the planting is done is advisable; for this I would prefer Cocoa-fibre to manure, as the birds would not be so disposed to interfere. Secure all the shoots then at once, or they may be injured by the wind, "caulker" afterwards setting in upon any gross shoots if damaged in this way. R.

3280.—Exhibiting Roses.—The National Rose Society does not make any hard-and-fast rule relating to the sizes of boxes when exhibiting Roses—they simply make a few suggestions. As a member of the society, and an exhibitor for some years previous to its formation, I have found the following dimensions all I could wish: For twelve Roses my boxes are 2½ feet long, 2 feet 3 inches wide, and 18 inches deep. One foot of the depth is taken up by the lid. This is where it is most wanted, as you thus afford ample room for the blooms. On no account have any boxes that are made on a bevel, or higher at the back of the bottom part than the front (as in the illustration). Your flowers naturally want to be

rose-coloured H. P., very sweet, the old General Jacqueminot (crimson, but exceptionally sweet), Noisette Lamarque (which requires a south wall), Marchal Niel (also needing a warm position, and better under glass than outside), and such H. P.'s as Mme. Clemence Joligneffix, Alfred Colomb, A. K. Williams, and Mme. Gabriel Luizet, whilst all the Teas are more or less fragrant.—C. T.

FERNS.

CHOICE FERNS.

TRICHOMANES PLUMA.

This feather-like Trichomanes is an exceedingly delicate and beautiful species; it has a wiry creeping rhizome, clothed with black hairs, and the fronds attain a height varying from 1 foot to 1½ inches; they are three or four times divided, the segments being very slender, as a glance at our illustration will show. This Fern has always been scarce in cultivation, but its rare beauty should be a sufficient inducement for its greater popularity. Like all this class of Ferns, it requires an atmosphere heavily charged with moisture, exclusion from the sun's rays, and a temperature which does not fall below 60 degs. at any season of the year.

G.

POTTING GOLD AND SILVER FERNS.

THE recent bright weather has enlivened things considerably, so that I must recommend my friends who from time to time write to me not to forget these Ferns when the time comes round. Now the young Gold and Silver Ferns are beginning to grow again after the dull, cold days we have had, and all may begin to make ready to set them going again, and to make a really fine display of these Ferns, I would advise the use of last year's young seedlings. Plants which are now occupying a 4-inch or a 5-inch pot should have a shift into one two sizes larger. These pots, well drained and a layer of Sphagnum Moss placed over the drainage, should have for soil about half and half good turfy loam, tolerably light, and good fibry peat, added to which should be some sharp silver sand and a little bone-manure; but this should be well broken, no large pieces of bone being left whole, but yet it should not be quite reduced to a fine powder, because it stands the chance of being washed out of the pot. In the growing season Ferns do like a little stimulant, but this should not be given in excess. Another thing which I have found to work wonders with the weaker Ferns is the use of broken bones for the drainage material. Try this, my friends, and tell me if it does not bring about a marked change. The plants of Gymnogrammas should not be tolerated in a fernery more than about two years, after which time they become too sticky and rough at the base, and a young plant is far preferable, and, if potted in the manner described, they soon make nice specimens. In selecting the kinds from the young plants pick out those which display the brightest colours, and the kind called chrysophylla presents many varieties from seed, and the brightest and best only should be permanently used. *O. sulphurea* is a pretty constant kind, and, although pale coloured, is a perfect gem, when well grown. The same may also be said of *G. Harminari*, although somewhat less pronounced than chrysophylla.

G. Lauchiana is a good robust form of the last-named species, well deserving attention, whilst *G. obrysophylla cristata* is a very fine variety, with dense corymbose heads, and the form known as *O. luteo-alba* is a broad, massive-looking plant with a heavy farinosa yellow coating on the under side; but I have only seen this in some gardens in the neighbourhood of Berlin, but it is a variety well deserving more extended cultivation. In *G. calomelana* and *G. tartarica* we have the fine Silver Ferns, which, however, vary very much, and require selecting in a young state, and, in fact, the first-named plant I have seen quite distinct of farina. *G. pulchella* is a beautiful plant, with finely-cut and very white farina on the under side; and *G. gracilis*, which I first saw in a Hamburgh garden, is quite a gem, being finely divided, very symmetrical, and covered below with a copious white farina. *G. Wettonhalli*, and is a crested variety, coated with a sulphur powder, and *G. decomposita* is another species, although not

heavily coated with farina, yet claims a place for the grace and elegance of its finely-cut fronds, whilst *G. peruviana argyrophylla* is noticeable for its pendent fronds, which are heavily coated on both sides with white farina, and at others with a sulphury-tinted coating. *G. Pearcei* is another species, with remarkably elegant fronds of a rich-green, and delicately divided, which must not lack a place in the cool fernery, for it comes from Fern, although it has no farina, saving at the base of the stripes; and last, but not least, is the fine variety of *Schizophylla* called *gloriosa*, which is one of the most elegant Ferns in cultivation, either for a hanging-basket or a pot, either with its long, arching, brilliant green fronds, which become proliferous at the apex, and its pinnae are very elegantly divided, and I think it really looks at its best

of square or oblong form, on the ground that he gets more views of the contents, but, provided they are the proper sort and well planted, they will do as well in one as in the other. When planting his Ferns, my neighbour brook up some light coke into pieces about the size of a Walnut, and laid them at the bottom of the case to assist drainage. On this was placed a mixture of peaty soil and Cocoa-nut-fibre, the proportion being two of the peaty soil to one of fibre. In this a few Ferns were planted, but not thickly, and they soon commenced to grow freely. Almost all our native Ferns will grow in a case of this kind, and not a few introduced species also, so the planter can make a choice to suit his own tastes. Water is seldom required, and if the door be kept nearly constantly closed but little evaporation will take place. As a matter of course, the supply of water must be regulated by the season of the year.—D.

CHRYSANTHEMUMS.

3200.—Old Chrysanthemums.—

"H. M. C." must not expect to have large blooms and still have the plants bushy. He can have them dwarf and have nice blooms, though the distinction between dwarf and bushy lies in the fact that the latter have numerous small shoots, whereas the former have but a few, and these upright, not depressed as in the bushes. When the shoots are 5 inches high take out the point of each, this will check the upward tendency of the growth and induce the shoots to increase in number. Restrict the growths to two on each shoot and repeat the topping when they make 5 inches more growth. After that allow them uninterrupted growth, thinning the shoots to three on each main branch which will result in those plants with six growths from the bottom, carrying eighteen blooms and so on. One bloom to each shoot is sufficient to give good results when the quality is of more consequence than numbers. The bud which forms in the centre of each shoot always gives the best results; all those which cluster about it ought to be early removed. Old plants like those of "H. M. C." will require more attention to watering and supplying with stimulants than young ones. They have so many more roots, and these absorb the nutriment contained in the soil so readily.—E. M.

—If you only want a dozen flowers to each plant you may stop the present shoots at 3 inches or 4 inches in length, and when in growth again shift them on into 10-inch or 11-inch pots, allowing one bloom to each stem; but if you want something uncommon, and have the space to house them, stop the growth twice or thrice, shift the plants on until 15-inch or 18-inch pots are reached, tie the growths out carefully, and feed liberally, leaving three or four buds on all the best shoots. In this way I have had plants of Mrs. Bungle, Mrs. Dixon, Fair Mail of Guernsey, and others 5 feet to 6 feet through, and carrying between 200 and 300 good blossoms apiece—not perhaps good enough for exhibition, but fine for cutting, and producing a splendid effect in the mass.—B. C. R.

3245.—Classes of Chrysanthemums.

—You will find the varieties mentioned in the catalogue of Mr. H. J. Jones, Rye-croft Nursery, Lewisham. *Le Poete* de Chrysanthemes (rose-violet and silvery-white), Mme. de Dubor (white, with stripes and blotches of violet-rose), and Mme. Dufosse (crimson-red, the petals with stripes of gold and tipped with the same colour) are early-flowering Japanese kinds, whilst *Strathmeath* is an American variety, one of a set of new early kinds sent out by the American raiser, Mr. Thorpe, and described as a cross between Nichols and Mme. Desgrange, the flowers of a very distinct new shade of rose-pink, and of good size, being produced at the end of September.—C. T.

3287.—Enclosing a garden with wire-netting.—I am doubtful about the wisdom of keeping birds out of a fruit garden. I have seen it done and it did not pay. The trees became so badly infested with insects that it was thought better to let the birds have their share of the produce for the help they rendered in keeping down insects. If any garden without birds would not be a profitable one—at any rate, I should have more trouble with insects and

Trichomanes pluma.

when in a hanging-basket. There are a few other species, and a lot more varieties, which I could have called attention to if I had thought it was necessary, but this will be enough to satisfy my readers I have no doubt. Now with these plants coated with a farina which can be moved off the fronds with ease, my friends must understand the syringa must be kept quiet, or if used it will make a blurr in the whole lot; therefore, although maintaining a nice moist atmosphere, never let any water be used upon the fronds, but maintain a temperature not lower than 65 degs., and your Gymnogrammas will grow and do well. J. J.

Ferns in cases.—A neighbour of mine, who has been highly successful in growing Ferns in a case, prefers one of octagonal shape to that

should lecur a heavy expediture is insecticides and washes. It might, of course, be managed so that the birds could have free access at all seasons, except when the fruit is ripe, or for a month or two when the buds were on the move early in spring, and in one instance where this was done the netting was thought to be a success. Two-inch web would be too large for the top, as small birds would get through it and eat the buds in spring.—E. H.

—2 inch mesh would keep out Blackbirds and Thrushes, 1-inch would keep out all birds, excepting the small warblers and Tits; but to ensure your garden against all fruit-eating birds you must use 1/2 inch mesh.—A. G. BROWN.

ORCHIDS.

MASDEVALLIA SHUTTLEWORTH.

I HAVE seen this plant recently doing so well and flowering so freely, and its blooms are so pleasing, that I am persuaded to recommend it to the growers of such plants as *Odontoglossum Alexandrie* and *O. Pescatorei*, for in such a temperature as these delight in this *Masdevallia* also does well. It is now nearly twenty years ago since this plant was first found by my very old and good friend Mr. Shuttleworth, while engaged in collecting plants in New Granada for his employer, Mr. Bull, of Chelsea, and at that time it was considered very rare. It has, however, been found in some considerable numbers since then, and has been introduced successfully to our gardens, and, therefore, I bring it to your notice. When I first saw it in flower, which is fifteen years ago this very month, I thought it then, as I do now, one of the most lovely gems in the whole family of Orchids. It has been made to suffer somewhat in its character of specific rank by being made to fall in as a variety of *M. caudata*, which is a plant that was named by Lindley upwards of sixty years ago, and it is only conjecture that the present plant does belong to *M. caudata* at all, so that I am quite in accordance with Hooker, who published a figure of this plant in the *Botanical Magazine*, t. 6, 372, and which, although capably rendered, does not do full justice to the plant—at least, I have now before me a more richly coloured and beautiful variety than the artist had in 1878. This plant was found by Shuttleworth growing on trees at an elevation between 7,000 feet and 8,000 feet above the sea level, and, consequently, requires cool treatment. The entire height, when out of flower, scarcely exceeds 6 inches; but when in bloom these stand up above the leaves, and add a little to its height, and the beauty is, as with the majority of these *Masdevallias*, lies entirely in the outer sepals, and of these the dorsal, or the upper one, is largest and coneave. The sepaline parts measure about 1 1/2 inches across; the upper one reddish-yellow, freckled with reddish-purple, and with numerous deep-red veins running up its entire length, the lower sepals being beautifully shot with rich purplish-mauve. Each of these segments is lengthened out into a slender yellow tail, considerably over 2 inches long, which makes the flower over 5 inches across. Another form has also been found named *Xanthoorys*; but this differs only in colour, and is not so pretty a plant as the typical one; the flowers are smaller, and mostly of a pale yellow. These plants require to be kept with the *Odontoglossum Alexandrie* and such-like plants, and, like them, they like to be kept moist during the winter; but, of course, much less is required than in the summer months, and they may be hung up, but the sun should not shine upon them. They should be well drained, and for soil peat-fibre and Sphagnum Moss in about equal proportions. My readers who have not this species will find it one of the most exquisite gems of the whole Orchid family.

MATT. BRAMBLE.

ODONTOGLOSSUM ALEXANDRÆ.

I AM requested by "Birmingham" to tell him all about this plant, and how to manage it successfully? This Orchid, it is said, was discovered by Hartweg, in the Province of Bogota, in the United States of Columbia, a little over fifty years ago, and at the present time Mr. Shuttleworth, the renowned traveller and collector of plants from that region, would appear to have a favourite spot about Pacho for getting

fine varieties of this plant from. It grows at from 7,000 feet to 8,000 feet elevation, so that the plant under cultivation requires to be treated very cool, and under such conditions as we in former times should never have dreamed that Orchids would have lived; and this is one of the things that I think the collectors in earlier times were not straightforward in telling us—the conditions under which these plants were found—seed, consequently, so many plants from the earlier collections were lost; but now the mind of many amateurs seems to be running the other way, by wanting to grow them in the company of Cape and New Holland plants, and exactly under the same conditions; but this will not succeed. I consider the best kind of house in which to grow this family is a lean-to facing north, and this should be kept very moist during the summer season, and less so during the winter, but still moist; the plants to be kept fairly moist at the roots. The temperature of the house must not be allowed to fall lower than 45 degs. Some of my friends say 48 degs.; but the letter I find, although asserting the last-named figure with a loud voice, do not grow their plants to such perfection as my other friends who take the lower figure as the minimum. This is to be with a plentiful supply of fresh air at all times, saving in severe frosty weather, at eight as well as by day, for in a state of nature the plants are not excluded from the fresh air that blows about them, and the advantage of night air I learnt some forty years ago; so you take my word for it, I have proved it to be quite the best thing. The soil best suited for these plants is a mixture composed of good brown peat-fibre and Sphagnum Moss in about equal parts, and the pots should be well drained. Do not overpot the plants at any time, and if they do not absolutely want potting do not pot them now, for this I hold to be the very worst time to perform the operation, which should have been done in the month of October, and from now until the month of May will be the time to see them in flower. Now I hope my friend, who signs himself "Red Something," will be able to make a successful start with the two plants which he has bought, and anything I can add from time to time to assist him, I shall be very happy to do, if he will only ask.

MATT. BRAMBLE.

3234.—House rubbish.—This is rather an unusual case; the heap must contain some sort of animal matter to be so offensive. The best thing you can do is to cover it with a good thickness of earth, and leave it in that condition until the offensive smell is gone off. I should hope the rubbish-heap is not near any dwelling-house, or where anyone spends much time, as it must be positively dangerous to health to be in the vicinity of such a foul odour which must be given off by the decaying matter. I know that common garden refuse will create an offensive smell for a time; but I never knew it so bad but what a man could turn the heap or move it about. I have, however, had to do it many a time, and without any ill effects.—J. C. C.

3300.—*Funkia subcordata grandiflora*.—Perhaps the following will assist "Black Bess." *F. grandiflora*—at least, the plant I know under this name—blooms late in the autumn, and the flowers are sometimes cut off by early frosts. If planted outside it must have a sunny spot, sheltered, and a warm, light loamy soil. When potted up and kept in a light position in the greenhouse, and a good loamy soil used, it should produce its sweet white flowers in abundance. Your plants may require repotting, or the soil is poor, or the drainage disarranged, or similar drawbacks. Under the above simple conditions I have seen it thrive well.—O. T.

3279.—A garden shed.—If the wheels are left on the railway carriage and sunk in the ground a few inches or the ground made up around them, no other foundation will be required, and by no stretch of imagination could it be called otherwise than a tonant's fixture. If permanently fixed in brick work it is a question if the landlord could not, if he felt so disposed, claim it at the end of the tenancy. A neighbour has a railway carriage standing in his garden, the wheels simply let into the ground a little, and a very useful place it is. I believe the carriage cost £5, and is strong and durable, and with a little painting will last many years.—E. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 27, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply so will do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

3313.—Auriculas.—What is the difference between the show and the alpine varieties?—H. T.

3314.—Seed Potatoes.—I have a quantity of seed Potatoes well sprouted. Should I put them in pieces, or plant them whole?—J. F.

3315.—Culture of *Nertera depressa*.—Will someone advise me the best way to grow this plant, also the exact temperature it will thrive most freely in?—NARRARA.

3316.—Checker-tree.—Will someone kindly give me the proper case of this tree? It may not be spelt right. I cannot find it in the "Dictionary of Gardening."—CURIOUS.

3317.—*Frimula obconica*.—Can *Frimula obconica* be divided, and, if so, when should this be done? Has it any partiality as to soil? Full directions would oblige.—M. L. E.

3318.—Dissolving bones.—What is the best method of dissolving bones, and how should the solution be applied to wall-fruit-trees, chiefly Plum, Pear, and Apple?—J. S. A. BUCKERT.

3319.—A succession of vegetable crops.—Will anyone kindly tell me how to procure a succession of vegetable crops on a rather damp and shady piece of ground?—T. H. C.

3320.—Pitcher-plant (*Nepenthes Sedeni*).—I should be glad if anyone would give me a few hints of the culture of this plant, and the heat it requires, and does it require heavy syringing?—W. M.

3321.—Introduction of the *Fuchsia*.—Will someone kindly inform me when the *Fuchsia* was first introduced into England, by whom, and from what country?—J. SMITH, London.

3322.—Bellisids, or Daisy Eradicator.—Will anyone kindly tell me whether the "Bellisids, or Daisy Eradicator," does answer in destroying Daisies on a tennis-law?—CONSTANT READER.

3323.—Plants for a shelf.—Will someone kindly give me a list of plants suitable for a shelf which is difficult to water—plants which will not suffer if occasionally dried out, other than Cactus?—C. N. P.

3324.—*Sedum Sieboldi*.—Will some reader kindly give me information respecting this plant? Does it bloom well, and what kind of flowers does it bear, and when? Also what treatment should it receive?—SOMER.

3325.—*Saccolabium Blumei*, &c.—Would "M.B." or anyone else kindly give me a few hints on the culture of this Orchid? Is it a stove plant or not, and also state the culture of *Dendrobium album*?—W. M.

3326.—Grape "Gros Guillaume."—I shall feel much obliged if anyone would give me a few hints about this Grape, as I have heard it is not worth growing, but I have planted a young Vine of this sort this winter?—W. M.

3327.—Pig-manure in the garden.—To what advantage can pig-manure be used in the garden? Can it be used for Beans and Peas, Cauldifer, Cabbage, &c.? Is it wise to use this manure at the time of planting?—ENQUIRER.

3328.—*Adiantum Farleyense*.—I shall feel much obliged if anyone would give me a few hints as to the culture of this Fern, and what heat it requires? And does it require much water, and does it want syringing over head?—W. M.

3329.—Tinted Panis.—Will anyone please tell me something about Tinted Panis? Where they can be bought (near Kingston, if possible)? The best sort to grow, a dozen or so? The average price of the same?—E. PLUMBER UNITS.

3330.—Anemones from seed.—Will anyone kindly let me know when is the best time to sow Anemone Tulgens and Anemone St. Bridget seed to get them in flower next February and March, and how should they be treated? Locality, Ireland.—PADDY.

3331.—*Lavatera arborea variegata*.—I have some plants of *Lavatera arborea variegata*, raised from seed last year. They are very leggy. Can I cut them down, or must I throw them away and start again? Will the tops strike if put in as cuttings?—C. N. P.

3332.—Worm-casts on lawns.—Does anyone know of a suitable chain harrow or metal brush harrow to drag over lawns and scatter these, or will any machine-maker invent and perfect such an implement? The roll, used once a week, makes all smooth and tidy for two days when the worms raise up the cake of soil, and more so, and the lawn looks bad again for five days. If the soil is too heavy scattered the appearance would improve quickly.—R. WILKINS AT URBANA-CHAMPAIGN

3333.—Plants for a cool-house.—I have a small lean-to greenhouse without any heating. Will any of your readers advise me to plants suitable? Would Tomatoes succeed? It is sheltered nearly all round, and entirely on the north and east sides.—BOSTON.

3334.—Stove in a greenhouse.—I have a greenhouse heated by a brick fire. Will someone kindly tell me if I could use a Tortoise Slow Combustion Stove placed outside the house in place of the brick furnace, connecting it with the old fire inside?—TORONTO.

3335.—Rose "Star of Waltham".—I have a Rose which was described by the nurseryman who gave it to me as the "Star of Waltham." I see in the catalogue that this Rose is crimson; mine is a bright-pink. Are there two Roses of the same name?—ROSE.

3336.—Saxifraga longifolia, &c.—Will some reader kindly tell me the kind of flowers Saxifraga longifolia and Saxifraga pyramidalis bear, and at what time of the year? My plants are in pots in the greenhouse. What is the best treatment for them?—SAXIFRAGA.

3337.—Pine-apples.—Would someone kindly tell me when I must start to syringe suckers in 6-inch pots, and when I should report them? They are strong plants, and are healthy. And should I use troughs on the pipes, and state the heat the Pine plants should be kept in?—W. M.

3338.—Apricot "Moor Park".—Would someone kindly give me a few hints on the culture of a tree of this fruit? It seems to be making a lot of wood, and it was root-pruned two years ago, and we only had seven fruits from it last year. They do not do to Cornwall like they do upwards.—W. M.

3339.—Painting a window-box.—I am fitting up a window-box, and shall feel much obliged if you will kindly inform me what I shall paint or otherwise coat the inside with to preserve the same from rotting away with the action of the damp. I understand ordinary paint is injurious to plants?—G. S.

3340.—Propagation of Hydrangea paniculata.—There seems some peculiarity about this variety as to its propagation. I tried to strike the hard wood, but failed. The young growth I tried in a hot-bed; these damped off. Will someone kindly advise me the best mode of multiplying it, also as to its culture?—HYDRANGEA.

3341.—A plague of sparrow.—I am overrun with sparrows, which are most destructive, and do an immense amount of damage to almost everything in the garden—flowers, fruit-trees, and vegetables. Can anyone inform me of a remedy for these pests at once, easy and certain? Shooting in a small garden is, of course, out of the question.—M. L. E.

3342.—Euphorbia spiculans.—I shall feel much obliged if some reader will give me information respecting the culture of this plant, also as to the best method of training a plant in a pot? I have seen illustrations of plants trained in a very curious manner. My plant is a very small one, with one straight stem about 15 inches high.—EUPHORBIA.

3343.—Heating a greenhouse.—Would glassed stove-pipe socket pipes answer for heating a greenhouse with hot water as well as the usual iron ones? I think a few weeks ago "B. C. R." mentioned them to be used for a fire, so I should like to know if they would stand hot water, as they would cost considerably less than iron hot-water pipes?—ST. MARK.

3344.—A Tomato-house.—I have a house which I wish devoted to Tomatoes. I should like to know how high the borders should be to grow them in? My house is span-roofed and has a border all round, about 2 feet from glass. Is this too near glass to put in Tomato plants? When the plants are high, are they trained up the glass in wires?—J. F.

3345.—Culture of Chrysanthemums.—I should be glad of a few hints from "E. M. M." on the culture of Anemone and Poinpon Chrysanthemums, when they should have their last shift, and when the buds should be taken? Flowers are wanted for exhibition about the 10th of November. And a few hints about Chrysanthemum Mrs. Alpheus Hardy?—W. M.

3346.—Caterpillars on Gooseberries and Currants.—Will someone kindly tell me the best way of getting rid of caterpillars from Gooseberries and Currants, other than picking them off? I have tried syringing with soft-soap and paraffin-oil, a teaspoonful in a bucket, and thought I had got rid of them, but, alas! they are there again.—FACULTY.

3347.—A removable greenhouse.—As to a tenon's or removable greenhouse, will someone kindly tell me if I should make a frame of wood—that is, of planks screwed together—and should I build a brick wall upon the plank frame upon which to fix a lean-to greenhouse? Would the same be considered portable, and so removable? My plank frame would only lie upon the ground.—WATERBURY.

3348.—A Swast-vine Grape-Vine.—I planted a Sweet-water Grape-Vine last November against a 10-feet by 20-feet wall to the open facing the south-west. It is 6 feet high. I shall be glad of advice as to how I shall proceed? Should I cut it back or not? I should mention that I dug out the soil to a depth of 2 feet, drained it with broken pan-tiles, and filled in with yellow loam, leaves and bones, and planted.—H. C.

3349.—Varieties of Roses.—I should be much obliged to "J. C. C." or "P. F." if they could tell me if there is any possible means of telling the different varieties apart? The Noisette and the Tea seem to be closely allied; in fact, I have seen Myrobal Niel classed as a Noisette, also a Tea. The Bourbon and H.P. are not unlike. Any information as regards foliage or flowers to tell by will be thankfully received.—H. T.

3350.—Treatment of Tea-weak Stocks.—Will anyone kindly let me know how to grow German Tea-weak Stocks properly? I always sow the seed in a hot-bed about the 20th March, but when the seedlings come up and get strong, the stems all get black near the roots and the plants die away. This even occurs when they are transplanted from the seed-box into another box. Soil I use is a nice, rich, sandy vegetable loam, and the hot-bed commences at about 60 degs., with a decrease from that onwards.—FAVOR.

3351.—Building a greenhouse.—I should be very grateful if anyone would tell me how to set about building a new greenhouse? I wish to have it a span-roof, about 8 yards or 10 yards long, by about 4 yards wide? The principal point I want to know is—whether it is cheapest to build with brick or dressed stone? Also, would it be cheaper to have the frames, &c., made at home, than sending away for them?—ONE WHO WOULD LIKE TO BEK.

3352.—Cut flowers for winter.—Will someone kindly give a list of plants to produce blooms, mostly white, for cutting next winter and spring? What plants for that purpose could be raised from seed sown now or later; when should seed of the following be sown, and what treatment would they require for winter blooming: Heliotrope, Marguerite Carnation, Snowflake, Winter-flower or Tree Carnation, Mizonnette? I can command a good temperature.—G. S., Hants.

3353.—Horse droppings.—Would "J. C. C." or "J. D. E." kindly inform me if they consider fresh horse-droppings a good thing to mix with loam for potting from? Pelargoniums, or would they prefer well rotted manure from an old hot-bed? The latter is very well rotted indeed. Further, they consider it advisable to shake all soil from the said Pelargonium when the same seems a little mouldy or fugny from using leaf-soil in potting-compost?—ZONAL PELARGONIUM.

3354.—Fowls in a garden.—Will someone kindly say what I had better do under the following circumstances? My neighbour refuses to keep his fowls within bounds, but allows them to trespass in every garden around. I cannot afford to place wire-netting around my open wire fence, so it would cost me £2 or more. I have counted thirteen fowls in the garden at once, and it is useless attempting to do any garden work till the nuisance be stopped. Will some reader kindly advise me?—C. N. P.

3355.—Badly-shaped Azalea.—Would "J. C. C." kindly inform me the best way to treat badly-shaped Azalea indica plants? They are liberally covered with bud now, which are mostly at the ends of the branches. These (the outer branches) are taller than the middle ones, which have scarcely any buds on. Shall I shorten the long growths, and, if so, may I expect a good show of bloom next spring? I can give them a fair heat to start in, say 50 degs. at night, or more. An early reply would oblige.—AZALEA INDICA.

3356.—Treatment of Peach-trees.—Will "J. C. C." kindly tell me the treatment I should follow with regard to my Peach-trees? About once a month during winter I had the border watered with tepid manure water—they are now coming into bloom. I syringed a freely every mid-day, and never let the soil get dry. I should like to know, as far as I have done right? When ought I to use the syringe, and when the syringe very powerful would be injurious to the fruit ripening if I had a slight application of "summer cloud" applied to the glass? In one corner of the house everything gets scorched, and I find the trees that get some shade look much better and are flowering more freely than those fully exposed to the sun, but I have had no experience as to the fruiting. My trees are young, and did not bloom last year. If "J. C. C." remembers, he gave me some good advice about deciduous trees last year. My trees were then badly attacked, and the treatment advised certainly checked them.—IVY BANK.

3357.—Culture of Eranthis robusta, &c.—I wish to raise Eranthis robusta from seed. I should be glad to hear from those who have been successful in doing so of their method? How long the seeds were germinating, if the plants survived one flowering season, and, most important item (generally left out), in what country and aspect they were raised? I also wish to try several American novelties advertised as perfectly hardy. I shall be glad to have information about them, as most of them are quite unknown to me, and, from the absence of the botanical name, many of the names are difficult to trace; Clematis paniculata, the Yellow Calla, the dwarf ever-blooming Calla, Achillea grandiflora, the Mexican Primrose (crimson, pink, yellow, and white, described as ever-blooming, and with flowers in racemes). Is Ipomoea pandurata, described as having large tubers, really good, or only the large Blood-wed, as the old kind is a most mischievous thing to get in a garden? What is the Maecetic Vine, which is said to thrive out-of-doors or in a room, and to always succeed with scarlet and yellow tubular flowers? Is the Terebinth Zealanica really a valuable new room plant, which "will do well in the shade"? Has anyone tried Nelumbium speciosum (true Nile Lotus) from seed; also the Water Hyacinth, Pontederis Orseipae, and Nymphaea Zanzibarensis, all described as exquisite Water Lilies with huge leaves and blossoms which will thrive in a tub of water in a room or out-of-doors in summer?—NORWICH.

3358.—Cattleya Mendallii (Orchid).—This plant would be the ordinary course of things have a larger health than C. Percivaliae. But are you sure you have the two kinds true to name?—M. B.

3359.—Cattleya amethystoglossa (Newstart).—I can only account for the state of the Cattleya through your having an over-abundance of water in the air. The temperature has been somewhat too high for good winter treatment, but I do not ascribe any of the fault to that.—M. B.

3360.—Epidendrum oilolares (Orchid).—This is a species that I really do not know, but if you mean E. ciliare it should be treated exactly the same as the Cattleya with which it is frequently found. It is very pretty, although it does not produce a fine and showy flower, and frequently this is the best grower plant amongst an imported lot, and when its flowers open one feels a little disgusted with it, and hence it has become an outcast.—M. B.

3361.—Lycaste Skinneri (H. F.).—As you cannot find any reference to the above I may here say you may grow this plant with the Odontoglossums, but in the winter when the plants are enjoying a temperature of 50 degs. or even 60 degs. for some species. The Lycaste will be better if subjected to a slightly warmer tempera-

ture, say about 50 degs., and do not dry it, though of course less water is required during the winter months. By this means you will have your plants flower with their foliage, and not bare of leaves, as they will mostly be if dried. When in flower they must be used for indoor decoration without any harm arising; but the plants must not be kept wet.—M. B.

3362.—Cypripedium insignis (Am. Orch).—I should say that your plant was potted far too light, and that it was kept too dry. It should be potted in a mixture of peat and loam, drain well, winter freely, and do not supply with much heat; in fact, it may even be stood in the cool frame for the summer months. If you want to divide them do it at once, potting them firmly. Do not elevate the plants above the pot's rim. Place them in gentle heat afterwards, and shade from the sun's rays.—M. B.

3363.—Phaius grandifolius (Orchid).—This plant, originally found in the East Indies and Cochin China, was introduced into the island of Jamaica over a hundred years ago, and has long been a common wild plant there. You should report it after the flowers are faded. Drain the pot well, and use a mixture of peat and loam in about equal parts, watering it liberally, and keep it with the ordinary stove plants in a warm house. Your plant bids fair to increase, and to give you a great deal more pleasure. I cannot say that the ordinary type is handsome or showy, but as you yourself observe, the flowers are peculiar and charming. It is a plant that does not like sunshine, therefore shade it from the strong rays of that luminary.—M. B.

3364.—Cattleya losing their health (Orchid).—I do not know what has caused this loss of health, but you may depend upon it that a Cattleya Mossiae will not flower this season, that C. labata makes up its growth in the autumn and produces its flower-branch, and it requires to be kept cool and somewhat dry through the winter months, when, with warmer days, the flowers push through in the month of May. C. gigas Sanderiaca makes its growth and flowers upon it soon afterwards, at the end of summer or the beginning of autumn, and so if your plant is not pushing its new growth, add it all in your power. The C. intermedia should be flowering now, or a little later. I have also known this species to flower late in the summer upon the growths, then recently made, so this plant should be carefully nursed, for although an old species, it is a charming flower, and one well deserving every attention.—M. B.

3365.—Ferns for a stove-house (Fanny Fern).—The following kinds would make you an excellent display, give you ample material for cutting from to mix with flowers, and save your house from a common appearance: Adiantum cuneatum, A. macrophyllum, A. Farleyense, A. toerum, Aglaomorpha Meyenianum, Anemidictyon Phyllitidis, Asplenium dimorphum, A. myriophyllum, A. praemorsum, A. rhizophorum, Blechnum acrostichum, Cheilanthes lan-nosa, Densdalea Davalliodes, Davallia elegans, D. Lodd-leyi, Gymnogramma Calomelanos, G. chrysophylla, G. Peruvianum argyrophylla, Lomaria gibba, L. todes, Microlepia hirta cristata, Oleandra perfoliata, Dicolia hymenophylloides, T. superba. Beside the above, the following will do you much good to hanglog-baskets: Asplenium longissimum, Davallia decora, Cheilanthes spectabilis, Gonolophium subauriculatum, G. verrucosum, Notholaemus trichomanoides, which in various species and varieties of Stag's-horn Ferns (Platycoleum) may be used as bracket ferns.—J. J.

NAMES OF PLANTS AND FRUITS.
Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W. C.

Names of Plants.—T. Andrews.—1, Lycaste saccata; 2, Glanthera recurvifolia; 3, Aethurium Rothschildianum; 4, Pteris longifolia; 5, Toxicaria spectabilis; 6, Gardenia citrodora; 7, Magnolia fuscata; 8, Pimeles spectabilis.—P. T. Derby.—1, Dendrobium Wardianum; 2, Cymbidium Lowianum; 3, Lycaste Skinneri (richly-colored form); 4, Lycaste Harrisoniae.—Fanny Fern.—1, Pteris tremula; 2, Pteris cretica; 3, Asplenium Fabianum; 4, Diplazium decussatum; 5, Microlepia oristata; 6, Laticochilus maculata; 7, Laetia velutina.

TO CORRESPONDENTS.

J. H. Stone.—We do not know anyone who makes a business of carpet-bedding designs.—Enquirer.—Send name and address. The present volume of GARDENING commenced on March 4th last.

BIRDS.

CAGE BIRDS.

THE SONG THRUSH.—Few, if any, of our feathered songsters have a natural song at once so sweet and powerful as the common Thrush or Mavis. It is, indeed, the herald of spring, and may be heard pouring forth its full and vivid strain as early as the month of January should the weather be mild. It breeds early in the spring, the first brood being generally fledged by May. The nest is composed of twigs, Moss, and dry Grass closely interwoven, and upon this is placed a layer of cowdung, covered over with particles of decayed wood, cemented together. The eggs are usually five in number, of a light-blue, speckled at the larger end with black. A thick, close bush, often evergreen, as the Holly or Portugal Laurel, is chosen in which to construct the nest. The young birds are easily reared upon white bread, soaked in milk, and lean meat, minced fine, and mixed with it. As soon as they can perch they should be placed in

DOBBIE & CO., ROTHSAY.

VIOLAS

One plant of each of the following 12 fine named varieties for 2s. 6d. post free. PLANTS READY NOW. Arch Grant, rich ledg-blue; Ardwell Gem, sulphur-yellow; Blue-cloud, white, edged with blue; Bullioe, bright golden yellow; Countess of Kintore, blue and white; Countess of Hopetoun, pure white; Duchess of Fife, primrose, edged blue; Duchess of Sutherland, blue-mauve; Mrs. Kinnaird, snow white; Ravenswood, rich plum colour; Hostie, white and pink; Wm. Niel, pale blue-rose. Two plants of each for 4s. 6d.; four plants of each, 9s.

FLOXES

Our plants this spring are the strongest and best on record, all from the open ground. 12 in twelve very fine named varieties, 9s. 6d., carriage paid; 50 for 12s. 6d.; 100 for 21s.

DAHLIAS

Grand plants ready to April. Simple dozen of Show and Fancy varieties, which we seed, carriage free, for 4s. 6d. Equal value in the other sections. SPECIAL CHEAP OFFER.—Wallflowers, Sweet Williams, Golden Pyrethrum, all 1s. 3d. per 100. Choeice Forget-me-nots, Auriculas, Bitters compacta, Lobelia, all 6d. per 100. Carnations (mixed), Violet Car. Iceland Poppies, Phloxes, Fick Mrs. Sinks, Gaums, and Geraniums, all 1s. 6d. Double Gorman Walls, Bromptons, Fuchsias, Heliotropes, all 9d. doz., all free, P.P. List free.—G. H. GILK, Wilberton, Ely, Cambs.

PANSIES.—Sample doz. 1s. 6d. named, carriage paid. The free—A. CATBRIGHT, Tulsehoe, Coventry.

SATISFACTION GUARANTEED.

MY NEW DESCRIPTIVE CATALOGUE contains the very best Lists of Chrysanthemums, Pelargoniums, Geraniums, Fuchsias, Dahlias, Colons, Carnations, &c., worth growing. I shall have great pleasure in forwarding a copy on application, post free.

DAHLIAS (pot roots).—5,000 to select from, at the following low prices: 6 2s.; 12 3s. 6d.; 25 5s. 6d.; 50 12s. 6d. All different, and named.

CARNATIONS.—P. of Penchurst, 9d.; Dorothy Ann, 1s.; Firefly, 6d.; Glow, 4d.; Gloire de Nancy, 6d.; Mrs. Laird, 6d.; Redbraes, 6d.; Ruby, 6d.; Salisbury, 6d.; Crimisee Gloire, 6d.; Pink H. Majesty, 6d.; Early Bush, 6d.; each 1 of the above, 6s.

PICOTEEES.—6 choice varieties to name 3s. 6d.

CHRYSANTHEMUMS.—12 new and very choice varieties, 6s.; 12 choice exhibition, 3s.; 12 best decorative sort, 2s. Seed for List of upwards of 500 varieties.

PELARGONIUMS.—The finest fringed and spotted exhibition varieties, strong plants, 6 for 3s.; 12 for 5s.

GERANIUMS (Zonal).—Pearson's choicest varieties, to name, 6 for 2s.; 12 for 3s. 6d.

GERANIUMS (Double), finest continental varieties, to name, 6 for 2s.; 12 for 3s. 6d.

GERANIUMS (Ivy-leaf Double).—My Collection of these is one of the most in cultivation, 6 for 2s. 12 for 3s. 6d. now 9s. 6d.; 12 for 10s.

MARQUERITES.—Etoile d'Or, Frutescens, Halleri maxima, and A. coelestis (blue), 6 for 1s. 6d.; 12 for 2s. 6d.

HARRISON'S MUSK.—6 for 1s. 3d.; 12, 2s.

AURICULAS, ALPINE.—Nice plants from single pots, 12 2s. 6d.; 25 4s. 6d.

COLEUS.—12 finest exhibition varieties, brilliant colours only, 2s.; 12 good decorative kinds, 2s. 6d.; 6 for 1s. 6d.

FUCHSIAS.—12 good exhibition sorts, double or single, 2s.; 12 decorative varieties, 2s.; 6 for 1s. 3d.

DELPHINIUM BELLADONNA, most lovely shade of pale blue, 2 for 1s. 3d., 6 for 2s.

TROPEOLUM COMET.—4 for 1s. 3d.; 12 for 3s.

ASPARAGUS PLUMOSA NANA, 1s. 6d. each.

All post free for each with order. Send a small trial order for—

J. POWLEY, FLORIST,

PHILADELPHIA, NORWICH.

RARE OLD DOUBLE CRIMSON POLYANTHUS,

BEACONSFIELD type of Single Polyanthus, yellow, white, facy, and laced, 1s. 3d. doz. Pansies, best Scotch, named, 5s.; unnamed, 2s. dozen. Pinks named, 3s.; unnamed, 2s. Carnations (J. U. is the name of some of the popular sorts), named, 5s.; unnamed, 3s. 6d. doz. Gloire de Nancy, the largest Gloire-scented white, Old Crimisee Gloire, and Red Braes, the best Picotees for outdoors, 2s. 6d. doz. Auriculas, choice, 1s. 6d. doz. Begonias, 1s. 6d. doz. Camellias, best named, 1s. 6d. doz. Anglica, 2s. 6d. doz. Arum, Little Gem, 1s. 3d. each, the above all in strong plants. Mimulus moschatum, flore-plena (double Musk), 3 strong plants, 1s., post free.

Post free, each with order.

CROMBIE, Barrow-in-Furness.

"TO ENSURE A PERFECT LAWN" SOW GARAWAY'S

"ONLY THE BEST" LAWN GRASS. 1s. per lb.; post free for 1s. 4d.; or 4 lb. for 4s. 9d.; 20s. per bushel. Carriage paid to any railway station.

GARAWAY & Co.,

Durdham Down Nurseries,

CLIFTON, BRISTOL.

GARDEN SEEDS, GIVEN AWAY.

A patent Nickel Silver or Vulkite Patent Case (value 1s.) containing tablet on which is printed Catalogue for 1893, will be presented to everyone who sends for Fowler's Half-Crown Box of Vegetable and Flower Seeds, which contains:—1 Pint Peas, 2 best kinds, 1 pint Broad Beans, 1 pint French, 1 ounce each Mustard, Cress, Parsley, and Turnip; 6 packets assorted Vegetable Seeds, and 5 packets Flower Seeds, with Seed Catalogue, post free, 2s. 6d.

TO THE TRADE.—Patent packets Seeds, 9s. 6d. and 6s. 6d. gross. Boxes of 50 small packets, 7s. 6d. dozen. Seed for List.

CARNATIONS. SWEET PEAS.

EXQUISITE SWEET PEAS.—Following are the cream: Apple Blossom, Buttery, Boreton, Imperial Blue, Cardinal, Countess of Radnor, Orange Prince, Prince of Wales, Princess Beatrice, Mrs. Gower, Gower, Primrose. Per packet, 6d. mixed packets of above, 6d. 1s. Also Eckford's Superb Seeding Sweet Peas, 6d. 1s. packet, free.

CARNATIONS.—Straw, well-rooted, 1s. 6d. doz. Reynolds Hole, 5d.; Allot Avon, 6d.; Ruby, 4d.; Gloire de Nancy, 4d.; Bride, 4d.; Dundas (single), 6d.; Prince Arthur, 6d.; Mrs. Laird, 6d.; Salisbury (white), 4d.; Salisbury (rose), 4d.; Mrs. Murr, 6d.; Corney Grain, 6d.; Redbraes, 4d.; old Crimisee Gloire, White Gloire, Purple Gloire, 2s. 6d. doz. Pink Her Majesty, 7d. each.

Pyrethrum, finest Hinc, pure white, 4s.; Caprice Naras, green crimisee, 4s.; Gladiolus The Bride, pure white, 9d. doz. carriage paid. Cash.

RICHES, Florist, Sandy Lane, Chester.

SPECIAL CHEAP OFFER.—6 Geraniums, 6 Double Ivy Geraniums, 4 Fuchsias, 2 Abutilons, 3 Double Pelargoniums, 3 French Lavender, 2s. free.—A. TOMKIN, Florist, Glasgow, Kent.

STRAWBERRY LAXTON'S NOBLE, splendid quality, 2s. per doz. J. BARNARD, Motspur Hill Garden, Motspur, N. W. C.

URBANA-CHAMPAIGN

ROSES.

ROSES IN POTS.

THESE will now require a large amount of attention, especially as regards their water supply. Oeas allow their roots to suffer in this respect and mildew, green-fly, blind shoots, &c., may be looked for as a matter of course. I would give all growing plants weak liquid-manure in abundance. Weak and often is a much better maxim than strong and seldom. I have seen as many fine plants of pot-Roses quite ruined for the season by the too generous treatment many amateurs afford as by any other cause. If guano is used, do not add more than half an ounce to a gallon of water, and apply this doubly as often as if an ounce of this powerful fertiliser was used. Similar tactics should be used when applying natural liquid-manures, such as the drainings from a stable or cow-stall. Well diluted, and used more frequently, being much the safest as well as most beneficial plan. The ammonia arising from the use of natural manure is much better than any derived from artificial compositions. Very few subjects are more pleasing than a well-grown pot-Rose; but to secure this great attention to detail is necessary. They must be well-drained, so as to take plenty of water without any risk of the soil becoming water-logged and sour. The wood should be well ripened each season, and grown on very steadily during the first six weeks after pruning. Then it is absolutely necessary that they be kept clear from insect pests from the beginning. I do not mean that no flies should ever be seen upon them—this being almost impossible—but it is possible to keep the plants sufficiently free from these pests that no appreciable injury can accrue. At the risk of repetition, I must once more call attention to the great advantage of frequent syringings with a weak solution of any reliable insecticide, or even of clear soft water at a temperature of 70 degs. Care should also be taken that no draughts reach the young foliage, nor must cold water be applied to their roots. It frequently happens that the water-tanks in a house are at the coldest end, and when these are sunk in the ground, and probably covered over with boards to form additional standing-room for plants, the water is considerably colder than the atmosphere of the house, more especially during bright days like we have recently been favoured with. Now it is at such times that your plants need more water, and the root action is often choked by copious supplies of such a chilling fluid—frequently as much as 20 degs. to 30 degs. lower than the temperature of the house and the soil that the roots are revelling in. Let the water stand in the sun for a time before applying it upon bright and warm days. P. U.

3335.—Rose "Star of Waltham."—You have evidently got a Rose under the wrong name. There is not the least suspicion of deep-pink in Star of Waltham's petals, but only a deep-crimson. Pride of Waltham is crimson-

pink, with silvery shadings towards the edge of petals. Beauty of Waltham is another crimson variety, but not so deep as Star of Waltham, and of an entirely different shape.—P. U.

No, there are not two Roses bearing this name. The colour of the Star of Waltham is a deep-crimson, and a very effective flower. Your plant is certainly not true to name.—J. C. C.

PILLAR ROSES.

It is very evident if anyone wishes to test the hardiness of any Rose that is at all suitable for the purpose, that he cannot do better than to plant it as a pillar Rose. Of course, there are different positions in which they will be planted, some much more sheltered than others; but I have in my mind now those that are planted quite in the open, exposed as mine are to all the winds and frosts that occur. Under such conditions it is very clear that any Rose hardy enough to pass through the two severe winters we had previous to the one which is now leaving us, may be safely set down as hardy enough for any purpose for which they may be required for cultivation in the open. Judging only from the appearance of the growth, I must say that I am disappointed in the behaviour of some after five years' trial. The most hardy looking Roses are not always proof against the frost; Gloire Lyonnaise, for instance, is much harder than I took it to be, and so is Madame Plantier, both White Roses of some merit. Perhaps no one will be surprised to hear that Gloire de Dijon is quite hardy on a pillar, but all may not know that climbing Victor Verdier is equally so. I doubt very much if the merits of this Rose are sufficiently known, as it is equally as suitable to cover a wall as a pillar, and in point of colour, which is a rich-deep-crimson, we have no other strong growing Rose that can surpass it, and I doubt if there is one to approach it, and, to associate with it, Magna Charta has no equal. This variety will reach the top of a pillar 10 feet high and produce scores of very large flowers at one time, and continue producing a few blossoms until winter is near. Madame Isaac Perrière is similar in colour and equally as strong in growth, but not quite so hardy. Princess Louise Victoria and climbing Bessie Johnson I have had to cut down to the ground this pruning season, as the old stems never recovered from the injury done to them by the frost in the two previous winters. Madame Nisobury has behaved splendidly as regards enduring the action of the cold, but I should like it to be a little more vigorous. Her Majesty has braved the frost unharmed; the growth is, however, somewhat sparse, but the flowers are exceptionally large, and the plant invariably produces two or three blooms in the autumn. Bonle de Neige grows fairly well, but is too tender for an exposed pillar. Charles Lawson is disappointing. The plant is hardy enough, but the quality of the flowers is inferior. I had expected something good from Madame Clemence Joigneaux for a dwarf pillar, but the growth is not vigorous enough, at the same time I doubt very much if many who know Roses well would have recognised the flowers that my plant produced two years ago; they were so large and full, and the shape exquisite. J. C. C.

3349.—Varieties of Roses.—The question asked by "H. T." is a very difficult one to answer. As he says, the Tea-scented and Noisettes are much alike; so much so, in fact, that more than one variety is classed as both. We find both Marechal Nief and Caroline Kuster classed as Teas, and also as being Noisettes. Personally, I fail to see the distinction between these two classes. The original Noisettes were rampant growers, bearing clusters of small blooms. We now have many Teas that bear clusters of flowers equally as freely as the Noisettes; the perfume is the same—so, too, is the growth—and for my part I fail to see any necessity for two classes, nor can I see where the distinction is drawn. Caroline Kuster is not a rampant grower like Almée Vibert or Miss Olegg, nor does it bear trusses of blooms any more than Madame Cosic, Madame de Tartas, and many more recognised Teas. Again, Gloire de Dijon is a Tea; but one of its seedlings (Bonquet d'Or) is almost always classed as a Noisette; yet it does not approach the ideal of the latter any more than that of the former class. In the case of the Bourbons and Hybrid Perpetuals, we find the same similarity in many cases. It is a very puzzling subject, and likely to become more so, as the National Rose Society has decided to constitute an additional class for Hybrid Teas. La France, Captain Christy, and many more that were hitherto classed as Hybrid Perpetuals, are now to be relegated to the new class. The Tea and China blood may be readily traced in many kinds that are looked upon as pure Hybrid Perpetuals, and I cannot help thinking Roses are subdivided far too much.—P. U.

I am afraid I cannot help "H. T." in this matter to any appreciable extent, as the distinguishing characters of the Tea-scented varieties and the Noisettes are not very easily defined. The latter are, however, much stronger growers, and produce larger clusters of flowers; moreover, they are on the whole harder than the Teas. There is a good deal of confusion in the arrangements of these two classes of Roses, but I do not know who is to blame for it. It is very clear, however, that a better arrangement is required. The Bourbon Roses are best known for the number of flowers they produce in the autumn.—J. C. C.

3287.—Enclosing a garden with wire-netting.—As you are only troubled with the birds during the fruit season I would not go to the expense and trouble of fixing wire-netting on the top, as a portion of it must be removed again in the winter to allow the ingress of the birds to destroy the insects and their eggs, which infest nearly all the fruit-trees. Stretch across from wall to wall some stoutish wire, and on these lay some 1-inch fish-netting, which can be taken down again in the autumn. One and a half inch mesh will be quite small enough for the wire-netting for the ends; the smaller the mesh the more expensive it is.—J. C. C.

3288.—House rubbish.—Dry earth is the best fertilizer, and this alone, with a sprinkling of lime, will soon make it quite harmless. Let the earth and lime be worked in as the heap is turned over.—E. H.

GARDEN WORK.

Conservatory.

Lillem Herriol will require frequent attention to keep the advancing flower-spikes free from insects. The insects are rather difficult to kill in the centre of the flower-spikes. The best remedy, I think, is a mixture of soft-soap and peaffin-oil, in a pall, in which the ends of the shoots may be dipped. This treatment will suit either plants infested with insects. A decoction of Quassia chips will answer the same purpose. Hardy shrubs, such as Lilacs, Deutzias, Japanese Azaleas, should not be turned out-of-doors when the flowers fade. The temptation to do so is great, as everybody is pressed for room under glass. I generally move them to a vinery that is coming on gently. Here a little pruning is given to put the plants into shape, and when new growth has been made the plants will be hardened off and plunged outside. Such plants will flower earlier and better next year. It would be economical, where much shrub forcing is done, to have a house no purpose to move such things to as they come from the conservatory. Selwonia Beni, Dietra, Lily of the Valley, and many other things usually forced will pay for kindly treatment after flowering. See that Pelargoniums forming flower buds are free from insects, so it will be difficult to clean them after the flowers open without injuring the blossoms. There is no better way of keeping these in a clean condition than by occasional fumigations with Tobacco. A stitch in time saves more than else. Young plants in full growth will require some regulation of their growth, stopping a shoot here and there at the right time adds to the symmetry of the plant, and gives compactness to the mass of blossom. In using stimulants it is not wise to begin till the roots are working through the soil. When they have consumed the bulk of the food in the soil stimulants—liquid and dry—will do good, but not much earlier. Look over the climbers every week now to thin out and tie in the shoots. In lofty houses Passies-flowers and Tacceolas should be allowed to festoon and dangle about a little shade will be necessary in hot weather. Bow Primulas and Cinerarias for early blooming. Osteosiles should have the plants, if they will not bear pricking in small pots, as drought is very injurious to them, and it is almost impossible to bloom them well and keep the foliage healthy in small pots. They will do best now in a cool-house where the sun cannot reach them. Cyclamens which have done flowering will do better in a cold pit, and be permitted to go gradually to rest. Prune any Camellias which are making much growth, and which have finished blooming. Camellia-blossoms are not much required now.

North House.

This house will be valuable now for retarding plants, or for keeping Azaleas and other plants which may be required for any particular purpose. It would be difficult for the exhibitor to thin his plants without a north house for retarding purposes. Heaths and New Holland plants generally will do very well in such a house. There must, of course, be the means of keeping out frost.

Keeps.

The hot sunshine of the past week has necessitated the use of shading for a few hours in the middle of the day. I am reluctant to begin shading before it is absolutely necessary, but when the plants are visibly distressed by the hot sunshine something must be done; but in no case should the shading be left no longer than is required, and at this season, so far as regards the day, the shading may be taken off by 2 p.m.; as the days lengthen the shading will be left on longer, but when the plants are in such a state that shading should be treated as a necessary evil, and be removed as soon as it can be spared. Plenty of water in the atmosphere is a necessity now; without this the plants would soon be infested with insects. When the plants are clean and in good health insects are not so troublesome. The above ought to be a very attractive house now. There will be a few Orchids in bloom among the Odontoglots, Dendrobiums, and Oeodictums, even where only a limited collection is grown. Amaryllis, too, are now showing flower-spikes, but these do best in the cool stove or intermediate house now, as the flowers are showing up. Give a little weak liquid-manure where the bulbs were not repotted. Save seeds from the good flowers, and hybridize to get improved varieties. The only chance of working up a stock is to buy a few good varieties of distinct character, and hybridize and raise seedlings. In four or five years from sowing the seeds there will be plenty of flowering bulbs.

Fernery under Glass.

The Ferns in variety are charming now in their new growth. The potting of specimens has, or should be, carried out, but with young, vigorous plants these will always be a waste of a shift. Do not overpot; small shifts are best. Tree Ferns are objects of great interest, but it is only in the large fernery where they are admirable. The Dicksonias, Cyathes, and others are so suggestive of the tropics that no large fernery is complete without some of them. I have raised several of these from spores, and though the young plants are useful for many decorative purposes, life is not long enough to raise Tree Ferns in this way, and neither is it necessary, as trees with trunks varying in length have now become a regular article of commerce. Those Ferns which do not produce fertile fronds will, of course, have to be propagated by division. I have done best by divided young plants; old specimens when cut up are a long time getting established. Like exhausted things generally, a good deal of re-culturing is necessary to keep up young stock taken from an old, exhausted plant. Keep pans of growing seedlings in a shady spot. If spores are raised the work should be done in a small house attached to the larger one, that can be easily closed when necessary.

Work in the Hot-bed.

This is a busy time in raising seedlings and striking cuttings. There is nothing in the way of plant propagation which may not be done in the hot-bed if the heat is sufficient and steady. Pelargonium alone will not do well in the hot-bed; these I always strike in a dryer heat. In striking cuttings or raising seedlings a good deal depends

upon having a good supply of suitable soil, neither too wet nor too dry. Where much potting has to be done, a stock of soil should be kept dry; and if, as is likely, it may get too dry, a little damp earth from the outside can be mixed with it.

Window Gardening.

Continue to sow seeds and strike cuttings, and to rapot any plants that may require more space. Keep pots clean, and use the sponge and soapy water wherever there is a suspicion of a green-fly. Divide large Aspidistras. Do not set Palms in the bright sunshine—in fact, fella plants are better kept in the shade when the sun gets hot. Window-boxes are now bright with Wallflowers, Forget-me-nots, Primroses, and Tofted Panicles. Where the soil is poor give stimulants.

Outdoor Garden.

Beautiful at the time of writing are the common hardy bulbs, especially where used freely on the Grass, on the lawn, or in the orchard, or wherever a quiet spot away from the scythe and mowing-machine can be had. The time of planting is not now, but notes may be taken of the best sites and best modes of arrangement for the autumn. A Grass slope at the foot of a house, or a not so good a spot, with a shelve, will always be natural and expressive. Snowdrops, I think, look better in broad, close tufts, so do also Daffodils, though there may be skirrhers thrown out from the main body. Aconites, in broad, close masses on shalving banks are always charming, and the pretty, blue-dowered Squill (Squilla sibirica), is still not plentiful enough. Iris reticulata on the rookery, with Anemone blanda and japonica on a bank, partially shaded by trees, are worth some little trouble to establish in quantity in order to attract attention. Violets for summer bedding should now be backed up and planted. Where there is plenty of scope in large gardens, the old varieties corata and lutes in masses are very effective. These flowers are small but freely produced, and in dry, porous soils, where the Panicles will not thrive, the small-dowered Violets may safely be grown. Pull to pieces and replant now. Even in backward districts Roses may be pruned now. There are many ideas upon, and much variety of treatment, in the pruning of Roses, but there is one point which is worth some little trouble to establish in quantity in order to attract attention. Violets for summer bedding should now be backed up and planted. Where there is plenty of scope in large gardens, the old varieties corata and lutes in masses are very effective. These flowers are small but freely produced, and in dry, porous soils, where the Panicles will not thrive, the small-dowered Violets may safely be grown. Pull to pieces and replant now. Even in backward districts Roses may be pruned now. There are many ideas upon, and much variety of treatment, in the pruning of Roses, but there is one point which is worth some little trouble to establish in quantity in order to attract attention.

Fruit Garden.

This is a good season for planting Meleser in hot-beds. With the increasing sunshine, which we hope to get, growth will be rapid. One plant in the centre of each light will be enough to fill the light, it set above the average also, though there is sometimes an advantage in having two plants in a light, as the crops may be set and swelling in less time. Rather strong loam is the best soil for Melons, and it should be pressed down firmly, as we want moderate, not gross growth. Where much Melon-growing is carried out, hot-bed or Melon-houses will be planted in succession as required, seeds being sown at intervals to have young plants always in stock. There are two chief difficulties in Melon culture—the one is their liability to be attacked by red spider, and the other is the "canker" which, in many cases, in dull, damp weather attacks the main stems. It is very difficult to keep soft, fleshy foliage free from red-spider, hence Melons should never be shaded, and the ventilation should be sufficient to keep the internal atmosphere buoyant and in motion. Where this is always done neither "canker" nor red-spider would give much trouble. "Canker" luxuriates wherever there is soft, blighted tissue and a stagnant, impure atmosphere. See that the blossoms of wall-trees are protected in the best and most economical manner possible. The blossoms are strong and healthy for the most part, and there is likely to be a good set with average weather. The sunshine of the last few days has made an improvement in early Vines. The sunshine hardens the foliage, and if the dry, fiercer heat is tempered by moisture being freely sprinkled about, the conditions of growth will be general. Prune outdoor Figs.

Vegetable Garden.

Cucumbers may be planted in frames where there is a steady bottom-heat of 30 degs. to 35 degs.; must be covered at night with double mats or some equivalent. Old rotten turf, mixed with a little old manure, is the best compost to plant to. A bush in the centre of each light will be sufficient to begin with. One plant in the centre of each light is better than two. On a raised bed will do very well. Stop and peg down as required, adding more warm soil as required. Do not permit any plants likely to be infested with green-fly to be placed in Cucumber-frames, but the frame may for a time be used for raising seedlings. Never use cold water, either for sprinkling or to water the roots. Prick off Calery in boxes or frames. Sew Vegetable Marrow and Ridge Cucumbers; or Pepinons also should be sown in the hot-bed, and New Zealand Spinach. As regards other varieties of Spinach, variety known as the Long Standing is most useful. Small sowings, according to demand, to be made fortnightly. Beans raised in boxes under glass, and which have been well hardened by exposure, may be set out on a warm border. Beans are improved by transplanting; they are more prolific. The best crop of early Beans I have ever had were started in boxes. Peas started to pots should also be set out, and well sheltered with branches and sticks, ridges of soil being drawn upon each side. Make new plantations of Globe Artichokes. Put out Camellias with the flowers, selecting the warmest sites. They will do very well in trenches in a sunny position where there are no bad-fights. Tie up Lettuces to frames to encourage early heading; but in doing this leave room for growth. The same remarks apply to early Cabbages; a bit of matting tied loosely round the leaves will fit the plants for cutting much sooner. Sow Turnip-Beet for early use. E. HODAY.

Work in the Town Garden.

Evergreen shrubs and trees may be planted at any time during the next month or so with the best results, care being taken to keep the roots well supplied with water and mulched in dry weather. Deciduous subjects of this kind may also, as a rule, be planted now with the best results.

the exceedingly mild weather we have been having for some time now has started those of a naturally deciduous nature, such as the flowering Currant, or Ribes, the Almond, &c., into growth and bloom unusually early, whereas these ought to be removed before much progress has been made. All of a later character may, however, still be transplanted quite successfully. Among Evergreen subjects, the Aucuba and Sycynnum are two of the very best for town gardens, thriving more or less well in even the smokiest localities; but the Skimmia, as well as the plain or green-leaved forms of the Aucuba, are also very suitable for such districts, and might be more commonly seen with great advantage. Other excellent town shrubs in this class are the varieties of Berberis, or Mahonia, the Arbutus, the Sweet Bay, the Rhedodendron, the Gum Clastic (which also produces its elegant blossoms freely), and the Tree Lilies, the last being especially valuable and suitable for any aspect or position. The strong-growing hybrid forms of Holly, with plain foliage, are also excellent for all but the most confined localities. Of deciduous shrubs some of the best for town gardens are the Ribes, the commoner forms of the Weigela, the shrubby Spiraea (several of which are especially beautiful, and good for cutting when or planted), Syringa, Philadelphus or Mock Orange), Lilac, especially the Persian forms, the Venetian, and Stag's Horn, Sumach, Leycesteria (fermosa), the double-flowering Cherrise, the varieties of Albion frutax (Hibiscus sylvicus), and last, but not least, the beautiful flowering Almond, though this last partakes more of the nature of a tree than of a shrub. In London and other southern cities and towns the Tree of Heaven (Ailanthus), and the Japanese Paulownia also succeed well, and are exceedingly handsome, and when the atmosphere is not too confined the Guelder Rose grows and blooms freely. Rhubarb is one of the best and most useful of all vegetables for a town garden, and when the roots have been protected by means of the proper pots, boxes, or even a little littery manure, there will be plenty of nice tender stalks new. Another plant that does not object to a smoky atmosphere is the Kale, of which seed should be sown, or root cuttings be planted at once. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from March 25th to April 1st.

Fruit-trees, Apples, and Peaches on walls are now in bloom, and are looking very promising. I am, perhaps, more than usually anxious about them, and have taken extra precautions for the blossoms. Britain's nettings are the best for covering I have ever used anywhere. These are fixed to a wire running along the top of the wall, with large hooks, which are sewn to the netting. The covers are supported by Ash-poles fixed 2 feet from the bottom of the wall. The net can easily be drawn aside like curtains and secured during the day to the poles, thus fully exposing the trees to air and sunshine. I find a double thickness of fishing-net, supported in the same way with poles, are just about as effective (so far as results go), as Britain's netting, and the former are the cheapest, both to first cost and the labour involved afterwards. Oatmeal ripe Strawberries from pots of both Vicomtesse de Thury and Noble. The first named is, in my opinion, the best ferocier, and the fruit travels better when packed. For long journeys the fruit is gathered before it is dead ripe, and the finishing touches are best given in a well ventilated house on a shift in the sunshine. Sir J. Paxton and President I had two of the most useful Strawberries for forcing, the British Queen is not too confined and confining. Any graft which fails in spring may have a bud inserted lower down the stock in August. Made alterations on a lawn, clearing off a few old shrubs, and making more space for herbaceous plants on the grouping system. These include rather a good collection of German Iris, which are planted in good-sized groups, edging several large beds with variegated Irises. The edging is raised a little, and the Irises are pegged down close to the ground. Ajuge purpurea in a bed outside; Salsify plants will form the edging to one bed, and the variegated Collin-leaf, and planted largely for summer use. The rows of Imperator 3 feet apart. Beauty of Hebron 2 feet 6 inches. Planting more Peas, the kinds being chiefly Duke of Albany, Walker's Perpetual, and No Plus Ultra. There may be other sorts as good, but the above will not fail to give satisfaction. Planted Taylor's Broad Windsor Bean to come after the Longpede. Planted dwarf French Beans in boxes to be hardened off, and planted in a trench in front of forcing-house. The position is warm, and Beans set out end of April invariably do well. They will be covered with mats at night. Sowing early Millar Turnip, putting sticks to Peas, Pricking out Lettuces and Brussels Sprouts raised under glass, sowing Broccoli, and Winter Greens generally. The seeds have been dressed with rad lead to keep birds from eating them. This never fails, as may be used with Peas and Beans where mice are troublesome. Pricked out oshoo seedling Columbinos in groups round a mass of shrubs on lawns. Tied down Vines and thinned Grapes. Thinned shoots on Muscat and Green Colman Vines, crowded foliage meaning small bunches (next year) shifted on young pot-bearers. Gave liquid-manure to Watered Figs in pots bearing fruit. Planted

In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

TREES AND SHRUBS.

BEST FLOWERING SHRUBS.

OLEARIA HAASTI.

This plant has now become one of the recognized stock shrubs in nurseries, and only a few years ago there was some doubt about its perfect hardiness in this climate. Now everyone knows, or should know, that it has not a suspicion of tenderness, as it has withstood without injury several winters quite unprotected. The peculiar value of this plant lies in the fact that it is one of the very few hardy shrubs that flower throughout August. If it blossomed earlier, when crowds of others were in bloom, it would probably not be so noticeable. Being an evergreen likewise adds to its value, and in almost all kinds of soils it thrives and flowers in the greatest profusion, particularly on light warm ones. So profuse are its white blossoms that the whole bush looks a mass of white, and this continues for three

ing between a pale-flowered Delphinium during early spring, so that it would flower at the same time as the Olearia. A dozen Larkspurs and six Olearias are sufficient for a good-sized bed. Another good mixture is Olearia and Orange Lilies, or Tiger Lilies, or Lillum venustum, but the Orange Lilies must be planted rather late in order to flower at the same time. A pretty mixture also is Olearias and Hypericum oblongifolium, which in its season blooms profusely, and whose large cup-like flowers of golden-yellow contrast well with the white. The Hypericum goes well with Olearia as regards growth, but being somewhat smaller should be kept at the margins. To give the group a better appearance, plant one or three Purple Cherry Plums (*Prunus pissardi*) among the others, but in the centre of the mass. The Scarlet Gladiolus *Brenchleyensis*, when in full beauty, combines effectively with the Olearia, and some of the most striking groups I have ever seen in a northern garden were of these two plants. Various other combinations will

and, as you will see, it does not kill the Daisies, but eradicates them in another way. It would be curious if we had a preparation that would kill Daisies and leave the Grass unharmed.—
J. C. C.

CHRYSANTHEMUMS.

CULTURE OF CHRYSANTHEMUMS.

3345.—Plants of Anemone Poinpon and Pompon Chrysanthemums should now be ready for potting off into 3-inch pots, providing they were struck two or more in pot. A good position on a shelf close to the glass in a cool-house for a week or so until the roots are running in the new soil; they will succeed afterwards in a cold frame. Providing a cool-house is not at command, they must go into the frame at once, placing it in a sunny position, admitting air cautiously for the first week or two, and covering the glass nightly to prevent injury from frost. From the 3-inch pots they should be transferred into those 4 1/2 inches in diameter, commonly called 48 size. From these they will go direct into those they are to flower in, 7 1/2 inches. The time when the last potting takes place is not so important as the state of the roots of the plants. When the 48 pots are full of roots then shift them on into larger ones. It would be most imprudent to allow the plants to become much root-bound in the small pots simply because a stated time was observed for potting them finally. The fault of allowing any section of Chrysanthemums to become matted at the roots before shifting the plants into larger pots is that the roots so quickly absorb the moisture in the soil as to require more attention in the respect of watering, and the progress of the roots is interfered with, which produces a check to the growth, and which is undesirable at all stages until the full growth is complete. As a rule, the final potting takes place at the end of May or early in June. A suitable compost for these sections in the various stages is two parts loam, one part leaf-mould or partly-decayed horse-manure, and sufficient sharp silver sand to keep the whole porous. The character of the loam—light or heavy—will guide this; if the latter, more sand is needed, and a small portion of crushed charcoal is an advantage, as it not only tends to keep the whole mass sweet and porous, but acts as a storehouse for ammonia. To every bushel of the compost add 1 lb. Thomson's Vine manure for the first potting, increasing the weight 1/2 lb. each stage. In all cases pot firmly; the soil should be in a moist state, neither wet nor dry. The plants will not need water for two or three days after potting if the soil is in the right condition. After that sufficient must be given to maintain the soil in a moist state. When the pots in which the plants are to flower are full of roots liquid-manure in a weak state will be an advantage if applied every other time the plants require water. At no time must they suffer for want of space. Overcrowding renders the growth weakly, and from such good blooms cannot be secured. At the end of August or during the first two weeks in September, the buds should be "taken;" so much, though, depends upon circumstances, as to the state of the plants and the manner of their growth, and also the variety as to the time the buds form. The dates named, however, are approximately true. Any variety in either of the sections named should produce at least six good blooms; for the smaller kinds, eight or ten would not be too many. When the first break takes place, instead of reducing the number of shoots to three, as in the orthodox plan, in the case of the Japanese and incurved sections allow four growths to remain; these will again break into additional shoots, and from them the number of blooms each plant is to carry can be selected—one only on a stem ought to remain; therefore, as many blooms as are expected that number of shoots must be retained. Mrs. Alpheus Hardy is perhaps the most difficult of any Chrysanthemum to manage really well; the constitution is weak, and therefore many failures have to be chronicled. The orthodox method so well suited to the bulk of other sorts will not answer for this. Exceptional circumstances have to be introduced to obtain even a fair measure of success. The cuttings should be inserted in good time to allow for a long season of growth. By topping this plants the first week in April buds will be produced in August. After the topping train

Olearia Haasti in flower.

weeks or a month. Out of flower it looks a good deal like the common Box, the leaves being of similar size, and shape, and colour, except that the under side of the leaves are covered with white down. The habit of growth is a dense rounded bush, and when planted out in the open it grows from 3 feet to 5 feet high, but gets much taller if crowded by other shrubs. The flowers look like tiny White Daisies, and the clusters that terminate almost every twig are very dense. This description of the plant is meant for those who do not know it, but these must be few, judging from the frequency with which it is met in gardens, large and small. No one need hesitate to plant it, but in doing so the shrub should be given a fair chance—that is, not stuck in a crowded shrubbery or on the fringe of one, so that it would be starved. Being so neat and compact in growth, it makes a capital lawn group in a good-sized oval or circular bed, and some very effective combinations may be made by planting, say, half a dozen Olearias about 2 1/2 feet to 3 feet apart, and plant-

suggest themselves to those who know the plants they are dealing with. It is a capital rock garden shrub, and does not mind dryness. The only other point I can think of about this Olearia is that the flowers are fragrant, and if cut and placed in water they last a long time in beauty. W.

3372.—**Bellicide, or Daisy eradicator.**—Yes, it answers in this way. If you can use it in sufficient quantity and repeat the application as often as necessary, it will make the Grass grow so fast that the Daisies are overgrown by it, and if this condition is the growth of the Grass is maintained the Daisies will disappear in time; but you will find it an expensive affair, as the fertilizing properties of the Bellicide quickly disappear, and, as I have already said, repeated applications are necessary before the Grass overpowers the Daisies. When a plentiful crop of Daisies are present it is an indication of poverty in the soil. This condition explains the action of the Bellicide.

up three shoots from the growths made by the cheek consequent on topping. The pots should not be quite so large in any stage of growth, as this variety is not so vigorous rooted as others. One part of peat instead of manure will be more suitable for the tender growth. Liquid stimulants ought not to be given in nearly the quantity as for others. As the wood is rather tender keep the plants longer than usual in the house in spring. Should flower-buds form at the point of the shoots towards the end of July, do not remove them, but allow the flowers to develop from them. E. M.

THE KITCHEN GARDEN.

VEGETABLE MARROWS.

The list of really serviceable or popular forms of Vegetable Marrows is by no means a long one, and no harm would be done if this was still

Long White Vegetable Marrow.

further reduced. Long Whites (here figured), of which there are several more or less good selections, is the variety most generally grown, this being good alike for exhibition, market work, and home consumption. If one variety only is grown, Long White should be that one. Long Green much resembles the foregoing in all but colour, and of this Prince Albert is a good selection. White Bush, also known as the Chusan, is of compact growth, the running growths in this case being very short, and this distinct form produces long white fruit very freely and quickly. It is not recommended for stering in a ripe state. Hibbert's Prolific each time I have tried it has been most disappointing; it was a failure, in fact. But Moore's Vegetable Cream is more deserving of a trial, the fruit being medium-sized, handsome, and good in quality. Muir's Pea-byd is, however, by far the best companion for the Long White, this variety producing small round fruit most freely, the flavour of these when cooked invariably giving satisfaction. Prior to the introduction of the last-named the Custard-shaped was grown for cooking in a small state; but this old free-bearing sort is now seldom met with. W.

POTATO CULTURE IN STIFF SOILS.

The best time of the year for planting Potatoes is now with us, and although it may be deferred as late as the first week in April with good results, it is undoubtedly better to get it completed before the end of March. It is well known that Potatoes may be grown in any soil with more or less success, and the following remarks are addressed principally to those who are obliged to cultivate this succulent tuber in stiff and unfavourable soils. The garden in which I grow my Potatoes is much shaded by trees, and this, combined with a deep stiff clay soil lying low and level, makes the tubers peculiarly susceptible to the dreadful Potato disease. Notwithstanding these adverse circumstances, I have lifted heavy crops during the last three seasons (two of which have been exceptionally wet during July and August) without much loss from this cause. I chiefly attribute my success to giving plenty of space between the rows

(2 feet for early varieties and 2½ feet to 3 feet for second-early and main-crop varieties), planting near the surface, and "earthing up" deeply. This latter detail has proved to be a most important one in the cultivation. The haulm makes strong growth, and the tubers develop freely in the freshly worked and friable soil, which they delight in, while the superfluous moisture is carried off by the deep furrows on each side of the row; this cannot be properly done unless plenty of space is allowed between the rows. The ground intended for this crop is deeply dug before Christmas, burying in it a heavy dressing of leaves which have lain in the pig-yard for a month previously. Before planting I run a garden hand-plough, with the cultivator attached, through the ground; this can be successfully worked by a pony where the area of ground to be planted is sufficiently large to allow of it. I then with the plough open shallow drills at the required distance, and in the rich soils of which I am treating the rows of the main crop should not be planted less than 2½ feet from row to row, and the sets 12 inches to 15 inches apart in the rows. When the sets are planted the drills are covered in with a draw-hoe. As growths appear above the surface, soil is drawn around them, and the cultivator is frequently worked between the rows to destroy the weeds and keep the soil open. Before the final "earthing up," which should be deferred until the haulms have grown to such a height that it is impossible to work the cultivator without injuring them, I sprinkle a light dressing of artificial manure between the rows. If Potatoes of exhibition size are required it is advisable to draw all the shoots from the sets, except the strongest; this will produce a few very large tubers to each set. It is now universally admitted, and it is also my own experience, that the best results are obtained from planting whole Potatoes of medium size. Of the early varieties I grow Sharpe's Victor and Myatt's Ashleaf; those two kinds were planted last year on the same date, in the same plot of ground, as an experiment, with the result that the former was ready to be lifted ten days before the latter, but Myatt's Ashleaf has the finer flavour. Of second-early varieties I grow Snowdrop largely, but I must admit that it is not altogether adapted to stiff soil; it is a delicate Potato, and liable to disease. Still, I have found that it may be grown profitably under the cultivation above described. Its white appearance and mealy flavour when cooked, combined with early maturity and good keeping qualities, makes it, in my opinion, the most desirable Potato of the present time. In stiff soils the old Magnum Bonum is undoubtedly the most profitable Potato to grow; its heavy cropping propensities and singular immunity from disease are well known, but unfortunately its cooking qualities are only second rate. Sutton's Abundance produces a heavy crop of handsome tubers of very high quality, but I have found it liable to disease, and this is the experience of several other growers whose opinion I have obtained. Satisfaction is a prolific Potato of fair quality which does well with me, and it is probably the most successful exhibition Potato of the day. Sutton's Supreme, sent out this year for the first time, promises well, and if its cropping and cooking qualities equal its appearance, it will take a prominent position in the Potato market. Everyone engaged in Potato growing must watch with interest the results of the experiments of dressing the haulms with strong solutions of copper, with the view of checking the disease, and while admitting that they appear to have been successful, it is, in my opinion, doubtful whether those who grow Potatoes for their own use will adopt such apparently dangerous remedies, and probably the best and most natural remedy against the disease will in the end prove to be high cultivation.

BRECHMAST, North Hants.

3319.—A succession of vegetable crops.—A damp and shady piece of ground is the worst place for producing a succession of vegetables, as it would be almost impossible to grow early crops upon it. The place would be useful in summer to grow green crops and salads, but only a very limited success would be obtained with Potatoes, Onions, or Peas. I have grown late Peas fairly well on a damp, shady

spot. Scarlet Runners, Turnips, Spinach (in summer), Cauliflowers, Lettuces, and Leeks did fairly well; and among fruits Black Currants and Raspberries. To make the best of such land one must plant only the crops likely to succeed upon it. Early Celery did fairly well, but late Celery, unless blanching with sifted ashes, always suffered from damp.—E. H.

3314.—Seed Potatoes.—Whether the tubers should be cut or not depends upon their size. If no larger than good-sized hen's egg plant them whole, otherwise cut each into two, three, or more pieces; but avoid cutting them too small, so the strength of the shoots, and, consequently, of the plant, appears to be almost directly proportionate to the size of the tuber, or part of a tuber, from which they spring. Take care to cut them, if at all, so as to secure one or two good strong sprouts to each, and lay them out in a dry place for a day, so that the cuts may heal before planting.—B. C. R.

—Better plant whole Potatoes if not too large.—E. H.

—You can please yourself. Every part of the Potato with a living eye will form a plant; and, in my opinion, you will get more return for your money by dividing than planting whole, as then each shoot will grow independently, and not rot or crowd its neighbour.—A. G. BOWEN.

3344.—A Tomato-house.—The height or distance from the giese of the beds in which the plants are grown is a matter of very little consequence. I have grown them in low structures furnished with raised beds where the plants were within a foot of the glass when put out, the growth in this case being trained to wires stretched transversely across the roof, while in lofty structures they are sometimes planted on the ground level, perhaps 10 feet or 12 feet from the glass, in both instances with good results. The position indicated in the question will do nicely. Tie up the stems of the outer row of plants to wires fixed 8 inches or 9 inches from the glass and the inner ones to upright stakes, taking out their points as soon as they reach the roof.—B. C. R.

3230.—Cauliflower and Broccoli.—By good management and with a sheltered garden a complete succession of these can be had the whole year. Of course, due allowance must be made for a continuance of frost during the winter, especially the month of January, when it would be difficult to obtain a regular supply of Broccoli heads at the time the plants are frozen without planting a batch in cold frames some time previous. The earliest Cauliflowers are obtained from plants raised in the autumn by sowing seed out-of-doors at the end of August, placing them in small pots and wintering them in a cold frame, planting them out on a sheltered border about the middle of March. Early London is a good variety for this form of culture. By sowing First Crop or Magnum Bonum in a gentle heat the middle of February, pricking them out in boxes of light soil, growing them on sturdily in frames, and planting out the first week in April a succession is maintained. By sowing Autumn Mammoth and Veltch's Autumn Giant outside the middle of April the former will give good heads in August and September, while the latter will continue the supply on through October and November, if dug up and laid in soil in pits or cold frames for protection from frost. Broccoli should be sown quite by the first week in April on a warm border, the plants put out early to give them ample time to develop thoroughly, and become matured in the stems, as it is in that part which the frost affects. So many persons postpone the sowing of Broccoli-seed too long, the consequence is that the plants have not time to grow into a size sufficient to give good results. No less than 2 feet of space should be given between the plants; nearer than that the growth is weakened, and more liable to suffer are the plants from severe frost. All the kinds may be sown at the same date. Michaelmas White will come in during the latter part of October and November; Sutton's Winter Mammoth in December, January, and February, while Leamington, Perfection, or Knight's Protecting will carry on the supply until Late Queen takes it up during April and May.—S. P.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

FERNS.

SOME CHOICE ADIANTUMS.

The accompanying illustration represents a very elegant Japanese Maiden-hair Fern, *A. monochlamys*, taken from a specimen gathered in that country by the late Mr. John Gould Veitch. Its fronds grew about 18 inches in height, of which about half is a naked, glossy, chestnut-brown stem; the frond is tripinnate; the pinnae distant; the upper edges rather rounded, more or less toothed; the texture firm and rather leathery; sori, singly on the pinnae, being situated in a deep hollow, whilst the colour is pale-green. It is a very distinct plant, and worthy of a place in every collection of Ferns.

A. FERGUSONI, another handsome Maiden-hair, is a beautiful companion plant. It has recently been introduced from Ceylon, where it has not, however, been found in a wild state, but was detected growing in a garden, nothing being known of its history. It appears to grow readily from spores, and retains its true character. The fronds are erect, tripinnate, and about 2 feet in height, and vivid green; pinnae large, irregular in outline, and deeply lobed on the upper edge. It somewhat resembles the variety of *A. Capillus-Veneris* called Footi.

A. SCHIZOPHYLLUM is also a pretty, neat, and distinct plant. The fronds are supported upon slender, jet-black stems, and seldom exceed a foot in height; they are much branched, all the branches being tripinnate; the pinnae are small, somewhat distant, and rounded above, where they are deeply toothed.

A. NELLUM is a tufted species with bipinnate fronds, which seldom exceed 6 inches in height; the pinnae, somewhat large for the size of the fronds, have short stalks, and are irregularly lobed and toothed on the upper edge, and bear two or three rather large sori on each. It comes from Bermuda.

A. GLAUCOPHYLLUM.—This is an elegant plant, and is considerably harder than either of the previously named kinds, which can be readily understood when I state that it has been found growing in its native country (Mexico) at an elevation of from 6,000 feet to 9,000 feet. The fronds are deltoid in outline, usually four times divided; the pinnae stalked and narrow; sori three to four on a pinnae when mature, chestnut-brown and conspicuous. Its fronds are light and graceful, and as they last a considerable time when cut, are valuable for table decoration.

A. FRAGILE inhabits limestone rocks in various of the West Indian Islands, and is, I believe, tolerably common in Jamaica, from whence I have received it upon several occasions. If in cultivation at the present time it is rare. It was introduced to cultivation by the late Messrs. Rollason, but did not attain any dimensions with them. The fronds are tufted, 6 inches to 9 inches high; stems slender, very short; pinnae stalked and rounded on the upper edge; the infertile pinnae deeply serrated, while the fertile ones are broadly lobed. This plant betrays the careless attendant more quickly than any other Fern I know. Its pinnae appear to be jointed to the slender stipes, so that if the plant suffers from drought the pinnae all fall away, leaving nothing but bare stems, which at once proclaim the neglect from which the plant has suffered. This character will at once prohibit the use of the fronds as a cut state, but when grown into handsome little tufts it is a veritable gem; indeed, the above-named half dozen small growing forms of the Maiden-hair Fern are amongst the very choicest of their kind. *A. fragile* does not like much soil about its roots, and requires to be kept in a very equable state of moisture. It thrives well in limestone. J. J.

3328. — Adiantum Farleyense.—This Fern requires a stove temperature, say, 60 degs. to 65 degs., at night, during its time of growth especially. It thrives best in good loam, and of too light a character; but good drainage is essential. Not producing fertile fronds, it can only be propagated by division of the crowns, and in working up stock it is better to rely upon young healthy specimens, as in this case they may be cut up into single crowns. When the plants are large the individual crowns are wide,

and if cut up into small pieces many of them may die, and, at any rate, they will take some time in getting thoroughly established. Where the atmospheric conditions are genial, either by the use of tanks or evaporating pans in the house or by damping covers, very little syringing is required.—E. H.

3277. — Sowing seeds.—It is not a very satisfactory way to mix up a lot of different seeds and then sow them broadcast without considering the effect likely to be obtained. It will prove a rare assortment, not particularly interesting or beautiful. I should advise you to sow carefully in clumps; but you may scatter such things as Poppies about with very charming effects in the wilder parts of the garden. As this is, however, an ordinary garden apparently you have to deal with, sow in clumps and masses, keeping each kind distinct, as *Mignone*, *Marigolds*, *Nasturtium*, *Larkspurs*, and the various other things that have been lately recommended in GARDENING. *Marigolds*, *Poppies*, and *Nasturtium* (*Tropaeolum*) would do well in the dry soil. Remember not to sow the seed too thickly, and thin out the young plants to sufficient distance apart for them to develop when large enough to handle.—C. T.

3313. — Auriculas.—The difference between show and alpine Auriculas is easily defined, owing to their quite distinct original parentage. The show Auriculas are supposed to be from Primula Auricula, a plant bearing trusses of yellow flowers, with a white centre, the white portion being covered with a fine white farina or powder. This white powdered centre is a characteristic of all the show Auriculas. Many of them have also powdered foliage, which the alpine never have. They are divided into four classes or sections. First, the green-edged varieties, with an edge of green on a dark-maroon or dark purple ground; second, the grey edge, with a fair powdering of farina over the green edge; third, the white edge, in which the powder is very densely placed on the edge, causing it to be quite white; fourth, the selfs, in which the edge is a solid colour of reddish-maroon, deep black, purple, bluish, or yellow. The alpine has probably been descended from *Primula pubescens*, a plant which was intro-

duced to cultivation some 200 years ago. There are typical forms of *P. pubescens* still to be found in the Alps of Switzerland and Styria; but they are said to be of hybrid origin. The best forms of alpine Auriculas have a yellow or cream-coloured centre entirely destitute of powder, or there may be a powder on any other part of the corolla. The edge is shaded, and in the cream-colour centres is of a purplish-tint. The others are usually maroon-coloured.—J. D. E.

— Show Auriculas are half-hardy greenhouse plants, the flowers of which are usually more mealy in character, or in horticultural dissection have thicker paste than their harder relatives, the alpine forms. The latter are absolutely hardy, and can be left out-of-doors throughout the severest winter.—A. G. BOLLEN.

3288. — Belladonna Lilias.—These flower very much better at the foot of a south wall than in pots. Hardly ever do they succeed when growing in the open border; they seem to need the warming influence of a south wall to enable the bulbs to mature sufficiently to give even a fair crop of bloom. The wall need not be a high one, but it should have a southern aspect. If the soil is heavy and retentive of moisture, dig out a trench close to the wall 15 inches wide and 18 inches deep. Place a layer of broken bricks, clinkers, or stones for drainage 6 inches thick. Over this lay some freshly-cut turf or freshly-gathered leaves to prevent the fine soil running down among the drainage, thus choking the passage-way for water. Fill the trench with equal parts of loam, peat, and leaf-mould. Cover the bulbs 2 inches with the compost, including the whole surface with leaf-mould 1 inch thick, which will act as a conservator of moisture during the summer. The end of October is the best time to shift those bulbs that have flowered the month previous. In "Black Bear's" case, though, I should say lose no time, but replant them at once.—S. P.

3332. — Worm-casts on lawns.—The reason why worms are so troublesome on lawns is because the lawn-mowers are usually set too low. Drop the front rollers so as to cut half an inch higher, and there will be no trouble with worms. Close-cutting ruins half or more of the lawns in the country. If the machine is set so as to cut higher a dense growth will form like the pile on a Turkey carpet, and the worms will not care to wriggle through such a mass of fibre to unload.—E. H.

3321. — Introduction of the Fuchsia.—There are something like fifty species of Fuchsias, and most of them have been introduced at various periods into England. The genus is founded upon a German botanist named Fuch, who flourished about the middle of the sixteenth century. The species from which popular garden varieties have been derived is probably *F. macrostoma*; and the first plant is said to have been brought to England by a seller, who gave the plant to his mother, and it was found growing in a cottage window, in the East of London, by Mr. James Lee, of the firm of Messrs. Lee and Son, Hemmermith, I believe about the year 1804. From this plant, which was freely distributed, probably all the varieties of the old globe, Moorcroft, and gracilis type are derived. It is a native of South America—Chili, probably. *F. coccinea* is a pretty species, also from South America—it may be Brazilian. *F. fulgens* is well known as a handsome, easily-cultivated garden plant. This was introduced from Mexico about 1830. *F. microphylla* is a charming species with small leaves and flowers, from Mexico. *F. splendens*, scarlet and green-coloured flowers, is a beautiful greenhouse species, and a recently-introduced species named *F. triphylla* from the West Indies is distinct and pretty. The New Zealand species, *F. procumbens*, is very distinct and pretty, producing small flowers and large berries.—J. D. E.

— According to the books, *Fuchsia coccinea* was introduced into this country from Chili in 1788. *F. macrostoma*, from which most of our present race of Fuchsias have descended, was introduced from Chili about 1823. There is a tradition that a sailor brought over the first plant as a present to his wife, and this plant was seen in a window in Wapping, and purchased by a London nurseryman (Mr. Lee, one of the early members of the Hammersmith firm), and the plant was propagated and distributed by him.—E. H.

3353. — Horse droppings.—I certainly do not advise you to use fresh horse-droppings for any kind of soil for potting, much less for Zonal Pelargoniums, which do not require a very rich soil. Good fibrous loam, and a free use of grit or coarse sand, is quite strong enough

A Japanese Maiden-hair Fern (*Adiantum monochlamys*).

duced to cultivation some 200 years ago. There are typical forms of *P. pubescens* still to be found in the Alps of Switzerland and Styria; but they are said to be of hybrid origin. The best forms of alpine Auriculas have a yellow or cream-coloured centre entirely destitute of powder, or there may be a powder on any other part of the corolla. The edge is shaded, and in the

for them. The hooter or Bronze Zonals require something lighter and richer, a little well-rotted manure or leaf-soll is suitable for mixing with the loam for them. With regard to the latter part of your question, I should say it is desirable to remove all the old soil when it is in the condition you mention. Even if it were not so, the plants will be benefited by having a change of soil.—J. C. C.

— Fresh horse-droppings would not be a good thing for mixing with soil for Zonell Peisgeraniums. The danger in growing these is to get the soil too rich, and fresh horse-droppings is very strong manure indeed. The well-rotted manure from an old hot-bed would do very well, and should be used at the rate of one-part of manure to four-parts of loam. Some leaf-mould and sand should be added. If the soil is mouldy and contains fungus—for mould is a fungus—it should certainly be shaken from the roots, as it would be sure to spread if this was not done.—J. D. E.

FRUIT.

FRUIT-TREES VERSUS FOREST-TREES.

FRUIT-TREES stand but a poor chance when brought into close contact with forest-trees, for the latter, being the strongest, especially in respect to their rooting powers, are sure in the end to get the mastery of the fruit-trees, so that if they do not kill them outright they at least reduce them to such a low ebb that the fruit they bear is worthless. If you go into almost any of the old gardens attached to the ancestral halls of England you will, as a rule, find the fruit and kitchen garden shut off and screened from the rest of the place by lofty forest-trees, with an undergrowth of evergreen shrubs, which have year by year sent their branches higher and their shade wider, and their roots in all directions in search of food, and although for some years after they were planted no great harm was done, it is now too plainly visible that the outer parts of the gardens are practically useless as far as any chance of getting either good fruit or vegetables is concerned, and it has often occurred to me that a fruit or vegetable garden, if at all well managed, needs no screening from view, for its occupants ought at all times to be as full of interest and quite as ornamental as the subjects used to hide it. I am well aware that wind-screens are valuable aids to fruit and vegetable culture, but if forest-trees are used for this purpose they will prove a far worse remedy than the disease—at least, if brought too close to the subjects to be sheltered. The roots of Elm-trees will run along just below the surface for at least 30 yards, and no forest-tree should be nearer than 100 yards to the trees or crops that are to be sheltered, as the shade from the branches causes weakly, unripened growth of wood, and fruit can never be of good flavour if it does not get the full benefit of all the sunshine our climate will give us; therefore, in giving shelter, we frequently do more harm than good by giving shade as well. In a great many gardens owners go on year after year putting manure to the roots of their fruit-trees, only for the hungry roots of the forest-trees that have taken possession of the soil to get the benefit of it, for so powerful are the roots in forcing their way through any hard substances, that I have found them pushing right through the joints of brick-walls that had been put down to keep them out of viney borders; in fact, the only way to be safe is to have no trees within a distance that is possible for them to reach your fruit-trees. I may also mention Ivy as a very strong rooting plant, and one that is often planted far too close to Vine and other fruit-tree borders, with the result that Vines have been nearly spoiled before there was any suspicion of the harm the roots were causing. If you desire fruit of good quality, see that the roots of the tree it is to be grown on has sole possession of the space allotted to it.

JAMES GROOM, Gosport.

3337.—**Pine-apples.**—I would not syringe Pine-apple plants at all—neither in the sucker state, nor in any stage of their growth. No plants are easier to grow when once their treatment is understood. The suckers should be grown on in 8-inch or 7-inch pots (with the

well rooted; after that plant them in the fruiting-pots. These should be from 10 inches to 12 inches diameter. Excellent Pines can be ripened in 10-inch flower-pots. Troughs on the pipes are not needed. I really think much evaporation from troughs does more harm than good. They require quite a hot-house temperature to do them well—65 degs. at night, with a rise of 10 degs. to 15 degs. more by day. The glass should never be shaded; as much light is needed as they possibly can obtain. In winter they rest by being kept dry at the roots, and in a minimum temperature of 55 degs. to 60 degs.—J. D. E.

— The night temperature for succession Pine plants now should be from 60 degs. to 65 degs., with a rise to 75 degs. before air is given. The syringe should be used on bright days only. Troughs on the pipes will be useful, as it will not then be necessary to damp the paths so often. Pines must have a moist, genial atmosphere from this time on through the summer, with a shade on bright days.—E. H.

3338.—**Apricot Moor Park.**—The tree is probably growing in a loose, rich border, and the best thing to do next autumn will be to lift it and replant, working a little old lime or plaster into the border. Lift carefully, with as little injury to the roots as possible; spread the roots out carefully in a horizontal position from 9 inches to 12 inches from the surface. Apricots and Peaches do best in firm borders.—E. H.

— If first dealt with when the tree has been planted three or four years, there is no tree that pays better for periodical lifting and replanting than this Apricot, but it resents root pruning. If carefully done lifting does not mutilate the roots so much as root pruning. Lifting also checks excessive growth without preventing the formation of fruit-bearing wood. From what I have seen of the behaviour of the Apricot in Cornwall you had better let your tree grow unchecked if you cannot lift the roots periodically as suggested.—J. C. C.

— The trees will make a lot of wood if they are grown in overrich soil, and when they grow too vigorously they do not fruit so well. As the tree has been root-pruned two years ago, there is nothing more can be done for it except to see that no manure whatsoever is given to it, and it will not make so much or such strong wood. When the tree gets into a good bearing condition, this will prevent its being too vigorous, and manure should be applied as a surface-dressing after the fruit is set.—J. D. E.

3348.—**A Sweetwater Grape-Vine.**—It is rather late to cut down the Vine now, as it might bleed to an injurious extent. The best thing to do is to rub off all the buds as they appear, except the two nearest the ground. As these grow train them vertically up the wall, and if the plant makes good growth these canes will be strong enough to bear fruit the next year. If you do not mind waiting a year longer for fruit a better plan will be to take the two canes down in a horizontal direction about 1 foot from the bottom of the wall, and in the following year train up a cane in a vertical direction about every 2 feet.—J. C. C.

— Bend the Vine down so as to get three eyes to break within about a foot from the bottom. If it was not so late I should say cut it down to within a foot or 15 inches of the base, and cut off all shoots but three. Of these leave the upper one perpendicular, and the other two right and left of the main stem at right angles about a foot from the ground. If the bottom shoots develop well, pinch the centre one when it has made 5 feet of growth, and let the bottom shoots make all the growth possible. From these bottom shoots will spring, in future years, other shoots which should be trained perpendicularly about 2 feet apart, and these will form the main bearing rods. It is a good plan to renew these from time to time by training up young shoots and cutting out a corresponding number of old ones.—E. H.

3326.—**Grape Groe Guillaume.**—Those who are fond of sensational bunches of Grapes should grow this variety. Bunches are produced up to 20 lb. weight, but one weighing even 10 lb. is a fine sight. The berries are quite round, but only of fair flavour. It is not nearly so valuable a kind to grow as Black Hamburg, neither is it so easy to secure regular crops. If the pruning is not carried out every year just, not so many of the growths are minus of bunches, whereas in the case of Black Hamburg

every shoot more often shows two and sometimes three bunches. If "W. M." doothes to restrain the cane, he should cut it down at once within two eyes of the base, to make sure of a stout growth. When the lower shoot can safely be said to be out of danger of stings, which are at times very troublesome, remove the top-growth, thus restricting the cane to one main rod. Encourage this to grow as far up the rafters of the house as possible the first year, pinching the point out of all side-shoots at the end of every second joint. In November next prune the cane to within 4 feet of the base. One of the side-growths pushing from the main rod will most likely show a bunch; this number will be quite sufficient for the first year. Continue the pruning of the leader in the same way until the limit is reached. Instead of pruning the side-growths every year to within an eye or two, allow every other to extend 6 inches long; from these the best bunches will be produced. The following year cut these back to within a single eye, and prune the others to 6 inches. By following this method of pruning every year a sufficiency of bearing wood is maintained. The greatest mistake cultivators make in growing this Grape is that of overcropping. If too many bunches are allowed to remain the berries will not swell to any decent size, neither will they colour satisfactorily. Even when the cane reaches the top of the house four good-sized bunches is an abundant crop, if these average 7 lb. each.—S. P.

— These who say that this Grape is not worth growing cannot have tasted examples that had been skillfully grown and ripened by the aid of fire-heat and kept to the following March, when it is very good and has a fine piquant flavour. At the same time, it is not a Grape that is suitable for general cultivation, and if you cannot give it the conditions I have indicated, and prepared to keep it until February at the earliest, you had better not attempt its culture. Young Vines bear indifferently, especially when the roots have the run of a deep and rich border.—J. C. C.

— This is the Grape usually grown as Barbarosa, or Black Barbarosa. Dr. Hogg found that the Barbarosa was quite a different and much inferior variety. It is certainly well worth growing, but it needs a high temperature, the same as Muscats, and plenty of room to grow. As the laterals push out to considerable length, there should be a space clear of 2 feet 6 inches on each side of the rod for the laterals to develop well. It produces very large bunches and larger berries, and although the flavour is inferior to some late Grapes, when well ripened there is not much to complain about in this respect.—J. D. E.

— This Grape is not equal to Gros Colman in any one point. It has a large, loose bunch, though the looseness may to a certain extent be remedied by shortening shoulders and cutting away the ends of the bunches. The Grape is a good setter, and may be grown in a lower temperature than Gros Colman. To make the Vines bear freely young rods should be taken up successively.—E. H.

3346.—**Caterpillars on Gooseberries and Currants.**—There is nothing like Hellebore-powder for ridding the trees of these pests. Sprinkle the powder over the trees in the evening, and vigorously syringe the trees with clean water in the morning to cleanse them of both powder and caterpillars. It is necessary to be careful in the use of Hellebore-powder, as it is poisonous, but there is not the slightest danger in using it if the trees are well washed afterwards.—S. P.

— Picking the caterpillars off is out of the question, and applying nostrums to the bushes is seldom effectual. As far as my experience extends, I believe the best plan is to dig the soil out from under the bushes and replace it with new soil from another part of the garden. This can be done in winter when the ground is being trenched in a part of the garden not too near the bushes. Bury the soil in the bottom of the trench, and replace it with soil free from the larvae of the caterpillar. Dusting with Hellebore-powder will soon kill them; but some escape from this and soon breed a numerous progeny.—J. D. E.

— As the saw-flies and meths, which are the parents of the caterpillars, are provided with wings, it is hopeless to expect by any process finally to get rid of these pests. You may also destroy caterpillars out of your garden one

year, but your next-door neighbour may neglect to do the same, and the insects produced from his bushes will lay eggs on yours, which will produce plenty of caterpillars for the following season. It is one of the singular facts about this world that dirt, disease, and vermin cannot be eluded away once for all by any process.—A. G. BUTLER.

3358.—Treatment of Peach trees.—No treatment could be better than yours, so far, providing you gave water enough at one time to reach all the roots. With regard to syringing, you may commence to do so as soon as the fruit is set; but do it gently at first, by which I mean do not use more force with the syringe than will nicely moisten the young foliage, or you may injure the tender skin of the young fruit. As the latter gets larger and the leaves stouter you may apply the water more vigorously, and if your trees are trained to a wall or on wires, get sideways when you ply the syringe, so as to get the water to reach the underside of the leaves. In the matter of shading, my advice is that you do not do as you propose, but let your trees have all the benefit of the sun, or the fruit will be sour instead of luscious and juicy. If your house is fully exposed to the afternoon sun you must vary your treatment according to the weather. When the sun is very

frame, and a few weeks later planted out where they are to flower. If your soil is light, you may succeed by sowing in the open. Three years in succession nearly all my stock have been killed by the frost, so that I am pretty well tired of trying to grow them.—J. C. O.

— Sow the seeds thinly on well-prepared beds now, either in shallow drills, or, if broadcast, cover with the sieve. Leave the plants to bloom where raised. They are bad things to transplant in a growing state; the check would probably prevent them blooming the first year.—E. H.

OUTDOOR PLANTS.

A FEW GOOD HERBACEOUS PLANTS.

MANY amateurs are deterred from growing any herbaceous plants by reason of the number of weedy, useless things that are highly extolled in catalogues, but bring nothing but disappointment to those who invest in them, while older, well tried subjects are hardly known. The following brief list, all of which ought to be planted without delay, are amongst the very best for good effect in the garden, or for providing material for the cut-flower basket—viz.:

ACHILLEA PTARMICA FL.—A beautiful plant that continues to flower all the summer, heads

summer, are strikingly handsome, the colours being soft and the petals beautifully serrated.

PHLOXES are too numerous to enumerate all the good sorts, but they are wonderfully improved of late, not only in finer bloom, but in dwarfier more compact habit of growth.

PYRETHRUMS, single and double, are amongst the best of all flowers for cuttings. Planted on good soil and the clumps divided at this time of the year, they continue to bloom almost the entire season.

PYRETHRUM ULLIGINOSUM is a splendid late blooming plant, the spikes of bloom on good soil reaching 6 to 7 feet high. It is one of the largest of the Daisy-like flowers, and being pure white, comes in most welcome for harvest festivals and other decorations. Where large masses of colour are required, it likes rich, moist soil, and should be transplanted every year.

TRITOMA OR KNIPHOFIA is a grand autumn-blooming plant, its stately spikes of bloom being produced very freely. *T. Burchellii* is one of the best varieties for continuous blooming. Well-managed mixed herbaceous borders form the subject of the annexed illustration.

J. G., *Hants.*

3329.—Tufted Pansies.—These are what the name implies, *Pansia* with a tufted habit of

OUR READERS' ILLUSTRATIONS: Hardy flower borders in summer at Osmanthorpe House, Newark-on-Trent. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. S. Kercheval Marsland.

bright close the ventilators at 5 p.m. instead of an hour earlier, and always syringe the trees at closing time, and in very hot weather damp the foliage again at dusk, so that the leaves remain moist all night. You may, however, be careful to open the house early enough in the morning (not later than 7 a.m.) so that the foliage may get dry before the sun reaches it. The corner of your house that gets so hot and dry must be specially dealt with, or red-spider will do serious injury. After well watering the border, cover the surface over 3 inches thick with a layer of sawdust or Cocoanut-fibre, and keep it regularly moist. Also syringe the wall and woodwork three or four times a day. As a further preventive measure against red-spider, get two or three slates and paint one side of them with sulphur mixed with milk, then suspend them so that the sun can shine directly upon them through the glass; the fumes given off by the sulphur are very obnoxious to these insects. If I can help you further, please write again.—J. C. C.

3330.—Anemones from seed.—I used to raise my stock of Anemones in the open ground by sowing in February or March, but I found the seedlings were so long in coming up that I now raise the plants in the greenhouse. My stock for next year is just coming up and when they are large enough will be picked off in other boxes, and afterwards placed in a cold

bed of pure white flowers, well adapted for any kind of floral decoration; it pushes out undergreened stems at this time of year, and soon forms large clumps.

CHRYSANTHEMUM MAXIMUM.—One of the very best of all hardy White Daisy or Marguerite-like flowers, as it continues to branch out and produce fresh blooms not only all through the summer, but right up to the time when frost cuts off all outdoor display.

HELIANTHUS MULTIFLORUS.—One of the best of Double Yellow Sunflowers, and, as its name implies, extremely floriferous; it makes a good background plant in mixed borders, and for cutting is excellent.

HARPALIUM RIGIDUM.—A very beautiful orange-yellow Single Sunflower, with very dark centre, attains a height of 5 feet to 6 feet in good soil, and continues to branch out and produce an unlimited supply of bloom.

IRISES, in great variety, are extremely beautiful plants, their fine foliage being very ornamental, while the colour of the blooms rival that of costly Orchids.

PRONIES have of late years become very popular, and deserve a place in every collection of hardy plants. The older sorts, with their massive crimson, pink and white blooms, are by no means to be despised; but the newer Continental varieties, that bloom mostly later in the

growth, which eminently fits them for adorning the flower garden and growing in a variety of ways. Since this came was given them they have become much more popular and many new kinds have been raised. Originally they were called *Violas*, and unfortunately many prejudiced people adhere to and use the old name, which, however, is unwarrantable, misleading, and confusing. Every true wild Violet or *Pansy* is a *Viola*, and one can find no justification for, but can see much confusion arising from, giving the true specific name to a particular race of garden hybrids of mixed parentage. The wild *Pansy* and many of the florists' show kinds have a loose, straggling habit of growth, but the Tufted *Pansy* covers the ground with a rich, more or less dense turf of shoots, and then becomes sheathed with blossom. It is quite one of the loveliest of spring flowers. Here is a selection of kinds, all of which I grow: *Abercree Gem* (clear, soft yellow with blue eye), *Archie Grant* (rich, plum-purple), *Ariel* (mauve-blue, one of the loveliest), *Countess of Hope-toun* (pure-white, without spot or marking), *Countess of Kintore* (purple and white, a striking kind), *Jackanapes* (upper petals crimson-brown, lower ones yellow), *Elegans* (laveder-blue), *Quaker Maid* (one of the best of all, soft mauve), *Skylark* (written with a distinct edging of blue round the petals), *Violetta* (white, dwarf, very tufted, very lovely), *Dand* and *Mrs. Grey* (crean-

white, an old but pretty kind. It is not usual to give the names of vendors, but as you ask for one in your district, with the Editor's permission, I might remark that in all probability you could obtain the kinds here enumerated at about 4s. per dozen in Mr. Barr's nursery at Long Ditton.—A. H.

INDOOR PLANTS.

3342.—*Euphorbia splendens*.—Preliminary speaking, this is a stove plant, but it will live through the winter in a warm greenhouse if the roots are kept dry from the middle of November to the end of February. The plant will, however, grow much faster in a higher temperature. It does not require much pot room, nor much water in the winter season. Good fibrous loam three parts, and sunnypeat, is a suitable compost for it, and it must have plenty of drainage. When your plant gets large enough, train it loosely to a few sticks in a natural manner as you can. Masly-bug is the only insect that troubles this plant.—J. C. C.

—This onions but exceedingly useful plant is naturally of a free and branching habit of growth, and may be trained in bush-form, a stout stick being placed to the main or central stem, and a few smaller ones to support the side-branches, as the head is naturally inclined to be heavy. I have also grown it with three or four stems only, these being not too formally bent round and tied to three or four sticks placed round the sides of the pot. It should be potted in light and rather poor and sandy soil, such as a mixture of loamy peat and sand, with a little leaf-mould and old mortar-rubbish. The drainage must be free, and the plant should not be overpotted. It succeeds best in the full exposure to the sun, no shade whatever being required.—B. C. R.

3317.—*Primula obconica*.—This grand plant is readily increased by division, and there can be no better time than when the bulk of its blooms are over. *Primula obconica* is almost perpetual flowering. Mine are being divided this week. They are also very freely raised from seed in the same way as *Primula sinensis*. I find the most suitable compost to be the following: Leaf-soil, one-third; loam, one-third; the remainder to be made up of broken charcoal, sand, and well-decayed manure. They enjoy a good supply of water, and are much best if kept partially shaded for a few days after division. There are few plants more easy to grow, or more generally useful for amateurs than this *Primula*.—P. U.

—The question is asked whether *P. obconica* can be divided? Probably it can, but the plants will do no good after. This species should be raised annually from seed, and, to do it well, it should be treated exactly like the *Primula sinensis* or Chinese *Primula*. I have tried it in frames and unheated houses, but it does no good, and should have a warm greenhouse. It is a very useful greenhouse plant, producing flowers all through the winter and early spring months; in fact, it is seldom out of flower. Pot the plants in a compost of loam four parts, leaf-mould one part, one part decayed manure, some sand, and a little fibrous peat. This seems to grow them admirably.—J. D. E.

—Divide *Primula obconica* when there comes a lull in the flowering, or, say, any time during April and May. Any good soil will grow this plant. It is very easy to manage; cold-frame treatment suits it best in summer, or it will do in the open air in a shady position. Plants from seeds sown now will flower next autumn.—E. H.

3324.—*Sedum Sieboldi*.—This *Sedum* was introduced from Japan in 1838. It is quite a distinct species, and makes a very pretty pot-plant, easily grown in any good soil. The flowers are produced in clusters at the ends of the shoots, and are pink in colour. The plants require the protection of a frame or cool-house in winter. It is easily propagated by cuttings, or by division of the root, or seeds.—E. H.

3352.—*Out-flowers for winter*.—Double White *Primulas* (Chinese), with *P. obconica*, *Gloxinia Snowflake* or *Her Majesty*, White *Cinerarias*, and the *Marguerite Carnation* "Snowflake" will be found very useful and easily raised from seed, which should be sown at once. Of the following cuttings must be inserted now or shortly—Double Zonal *Pelargoniums*, *Bouvardia Vreelandi*, *Abutilon Boule de Neige*, *Paris Daisy*, and *Chrysanthemum*.

Snowdrops, and others. You had better buy young plants of the *Trees-Carnations*, and shift them into 6-inch and 7-inch pots.—B. C. R.

3347.—*A removable greenhouse*.—I should advise you not to use any brickwork at all, beyond just a single row of loose ones laid down for the timbers (or "plates," as they are termed) of the house to rest upon. These "plates," which should consist of stout quartering—6 inches by 3 inches is a good size for a small structure—must be "halved" together at the corners, and the posts or uprights mortised into them. Fill in the lower part of the front or sides and ends with stout match-boarding, and the upper portion above the staging with glass.—B. C. R.

3351.—*Building a greenhouse*.—Whether brick or stone will prove the cheapest depends altogether upon what part of the country you reside in. If within a few miles of a quarry, stone will probably be the cheaper; if in a clay district, brick will come less expensive. It is the cost of carriage more than of the actual material that tells. You will find it cheaper to buy machine-made sashes, &c., than to have them made by hand at home; but as regards the roof, much the least expensive method is to get the wall-plates and ridge in place; then cut the rafters (formed of stout sash-bar stuff) to the right length and shape at the ends, and simply nail them in place at the same distance apart as the width of your glass. Of course a house so constructed is not so easily removed as one formed of sashes, but it is much cheaper in the first place, and lighter as well.—B. C. R.

3343.—*Heating a greenhouse*.—I have never used the glazed socket-pipes for hot-water work myself, but I saw an apparatus fitted up in this way in a small house not long ago, and was given to understand that it acted satisfactorily. I do not know of any reason why this description of pipes should not answer the purpose, the joints being carefully made with Portland cement.—B. C. R.

3333.—*Plants for a cool-house*.—Provided the house is fairly light and well ventilated, and receives plenty of sun, Tomatoes will succeed in it very well during the summer and early autumn months. You may put out strong plants from the middle to the end of April, according to the weather, and they should commence fruiting in June, and continue until out of off by the first sharp frost. Beneath the Tomatoes may be grown *Fuchsias*, *Begonias*, and, indeed, almost any cool greenhouse plants, from May till October; with *Chrysanthemums* in the autumn, *Christmas Roses*, *Laurostomus*, *Violets*, &c., in winter, and bulbs of various kinds in the spring.—B. C. R.

—In a warm position Tomatoes will succeed in an unheated house if not planted too early. If the plants can be raised and grown to a good size before and kept in the house is heated it will be more useful, considering the character of the seasons of late years. One of the best ways of furnishing a cold-house is to plant it with *Tea* and *Noisette Roses*.—E. H.

3350.—*Treatment of Ten-week Stooke*.—This fault—a kind of "shanking"—arises from imperfect drainage and an insufficient supply of moisture. You should place a full inch of bricks, broken small, or fresh coal-cinders, in the bottom of the seed-pans or boxes, with some rough siftings over, and keep the seedlings quite near the glass, with plenty of air, and then there will be very little "shanking." I always succeed much better with these *Stocks* by sowing on a greenhouse shelf in February than in a hot-bed in March. Keep the soil moist, and if a few plants should go off in this way, shake a little dry sandy soil among them, and prick off as soon as possible.—B. C. R.

3323.—*Plants for a shelf*.—*Echeverias*, *Air-plants*, and *Ice-plants* would answer your purpose. As regards the last mentioned, I considered them so uninteresting and even ugly that I tried an experiment with mine to see what they would bear. I stood them on the floor near the hot-water pipes, and never watered them for about three months, yet they still looked healthy; in fact, so much so that a neighbour who admired their peculiar ugliness asked me to let him have them, and thus I got rid of them.—A. G. BUTLER.

—Many plants succeed admirably on shelves near the glass, particularly during the autumn, winter, and spring. Of such are the *Thick-rooted* and winter-flowering *Begonias*,

Gloxinias, *Primulas*, *Cyclamens*, &c., but all these must be regularly watered as required, or they will do but little good. Beyond the *Cactus* and a few other succulents, such as the *Crasulads* (*Kaloesantbes*), *Rochea falcata*, *Sempervivums*, &c., there are very few things that will succeed if frequently allowed to become thoroughly dry at the root. Perhaps the *Ivy-leaved Pelargoniums* suffer less from occasional want of water than most others.—B. C. R.

—You might grow a collection of *Mesembryanthemums* (*Fig Marigolds*), of which there used to be many varieties in cultivation. *Aloes Gasterias* (*Tongue-leaved Aloes*), and other allied genera may also be grown.—E. H.

3320.—*Pitcher-plant* (*Nepenthes Sedeni*).—This is a garden hybrid belonging to a genus of plants requiring a very warm temperature and moist atmosphere. They do require to be syringed to keep them clean; but I find they will do without it if they have the moist atmosphere and temperature of 60 degs. to 65 degs. as a minimum, or even 70 degs. in summer. Water freely with rain-water if it can be obtained, rather warmer than the atmosphere of the house. They should never be quite dry at the roots, and succeed best in Teak baskets, suspended from the roof-glass.—J. D. E.

3334.—*Stove in a greenhouse*.—I do not see any difficulty in fixing a "Tortoise" stove so as to connect it with your existing flue, but whether the draught will be sufficient I do not know, and I am afraid that you would not get sufficient heat from a stove of a small size. Looking at the simplicity of the working of the "Tortoise" stoves, and the easy way in which they are fixed, I think your idea a capital one, and I thank you for bringing the idea to my notice, as should you find it answer it will be of great value for others as well as yourself. Anything that will increase the convenience of amateur growers always interests me.—J. C. C.

—Do you intend to use the "Tortoise" stove to supply heat (by means of hot-water pipes) to another structure? This can be done, but you will not obtain nearly as much heat from the flue in this way as with a brick furnace. The best kind of a furnace for a flue—at least, where coke is the fuel employed—is the deep square one I have so often advocated, and if a little heat is wanted for another purpose from the same fire I would make the surface round, and build in a small coil in the lower part.—B. C. R.

3355.—*Badly shaped Azaleas*.—If the plants are not old ones and the roots active, you may cut your plants into shape by removing the straggling growth, but I wish you to understand that there is a certain amount of risk in dealing with them in this way. Any plants in the condition I have stated would start into growth if cut back and afterwards placed in a temperature of 65 degs., but old neglected examples would be a longer time in recovering from such treatment. If you decide to cut them back you must do so as soon as the bulk of the flowers have faded, and place them in a warm-house at once, where they can be regularly syringed, and have a thin shade on the glass, and remain under this treatment until the young shoots have grown from 1½ inches to 2 inches long, when they will require more air to harden the growth and assist them to form flower-buds. Treated in this way, you should get a good show of bloom next year. If it was my case I should prefer to bring the plants into a better form by training the long outside growths to sticks so as to bring them more into the middle. If this is done when they go out of flower the plants would grow into a better shape before another flowering season comes round. This is the only way to make presentable specimens of such flat-headed varieties of *Azaleas* as youre.—J. C. C.

3325.—*Saccolabium Blumei* and *Dendrobium album*.—*Saccolabium Blumei* and *Dendrobium album* are both stove plants, and as regards temperature require about the same. *S. Blumei* may be grown either in flower-pots or Teak-baskets, planted in a depth of 3 inches of *Sphagnum Moss* and pot-herbs. If they are grown in flower-pots, the remainder of the depth should be filled up with clean crocks loosely placed in. The plants like to be grown near the glass roof, and to be protected from the sun by a thin shading. A temperature of 60 degs. suits them in winter, 65 degs.

to 70 degs. in summer; these are the minimum temperatures. They should be 5 degs. to 10 degs. higher in the day-time. *D. album* is misnamed; it is the *Dendrobium aequum* of Lindley, so named because of "its pale, watery-green flowers, quite destitute of colour." It was introduced first from Bombay by Messrs. Lodiges, and flowered in their nursery at Hackney in 1842. Dr. Lindley says it should be potted in rough, turfy peat, well mixed with pieces of broken pots. Fill the pots half full of peat-shards, and elevate the peat well above the rim, giving plenty of water in the growing season. Dr. Lindley's temperatures are right—50 degs. to 55 degs. in winter; 68 degs. in summer. It has been found quite recently by Major-General E. S. Berkeley, who found it on the Nilghiri Hills in Northern India, growing in quantities on old Coffee-plants. The rainfall there is excessive, as much as 10 inches in a day. Grow it in pots or baskets, and the usual peat and Sphagnum compost.—J. D. F.

WHITE FLOWERS FOR EASTER.

The near approach of one of the annual festivals when white flowers are in great demand calls for extra exertion and forethought, not only in

DEUTZIA GRACILIS is one of the most useful of all white flowering plants for spring-blooming. Plants that have made strong growths of well-ripened wood in the open air should be lifted in November, potted in good loam, and set in any cold-house or pit until Christmas, when they should be placed in a genial growing temperature, and by Easter every shoot will be a perfect wreath of the most lovely white blossoms.

EURYBIA QUENI, OR *OLEARIA GUNNIANA*, is a beautiful dwarf shrub, covered with white, star-like flowers, and needs very little artificial heat to get in bloom in March.

FREESIAS.—These beautifully scented flowers are now in great request, and if kept in quite cool-houses or pits will flower naturally about Easter-tide.

HYACINTHS, of all the pure-white sorts, are very effective either as pot plants or for cutting. For pot plants, three bulbs in a 6-inch pot look well; but for cutting, the bulbs grow just as well in boxes.

LILY OF THE VALLEY requires only a gentle heat to have it in perfection at Easter, and for cutting large clumps of good flowering crowns may be placed in boxes and brought on gently in any warm house. They start into growth best

useful of all decorative plants, or for supplying cut flowers in quantity; its light, feathery spikes look well and give a light, graceful look to any arrangement in which they are used. They are of the easiest culture, for with good clumps of crowns, potted in light, rich soil, and kept well supplied with water at the root, one can hardly fail to have good plants.

TULIPS are very effective, and easily timed to come in for any given date. They should be potted or boxed in November, and kept in quite cool quarters, and about a month before they are required can be placed in warmer quarters if not forward enough. White Van Thol, single, and La Candeur, double, are excellent kinds. JAMES GROOM, Gosport.

AUSTRALIAN FUCHSIAS (CORREAS).

My attention has been again called to these plants by the great beauty displayed by some specimens I have seen for three months in the dulllest time of the year. The colonists employ the leaves of *C. alba* for a drinking beverage, using them in the same way that we use Tea here at home; but those with gardening tastes love the plants of this family, as they remind them of the Fuchsias of the old country. With us here in England, some forty or fifty years ago, they were much sought after, their gay and brilliant flowers serving to decorate the greenhouse during the dull winter and early spring months; but of late years these plants have not found favour with the majority of plant growers, and it is only here and there we find places where they are grown at all, and, indeed, I think that the Messrs. Low, at their Enfield nursery, do more to promote the cultivation of the Australian plant than any other nursery firm in the country; but even there I hear great complaints from both employers and their salesmen about these and similar plants not finding a ready sale. One man said to me, pointing to some fine *Pimelea spectabilis* plants: "Even such things well laden with bloom as they are get a begging." But I hope that better times are coming, and that we shall again have the greenhouse plants as fine as they used to be shown by Mr. Green, Mr. Cole, and Mrs. Lawrence, and many others in their day; but then the atmosphere of London was better in those times than it is in the year of grace, 1893. These very pretty plants, the *Correas*, are evergreen shrubs, flowering mostly in the winter and spring months. They can be struck from cuttings, but the custom has become pretty general to graft them, because they do not appear to grow so vigorously upon their own roots. *C. alba* is a very fine one, and it has been fixed upon as the kind to select for a stock. When established they soon commence to grow, and to bring them into shape and make presentable they require to be frequently topped—that is, have the points of the shoots taken out; but as their natural habit is bushy, they do not want much training. They will require repotting soon, draining the pots well, and using for soil a compost composed of about two parts good peat, one of light yellow loam, and one of sharp silver sand. After potting they must stand in the greenhouse or the frame until they get well rooted, and after this they should be stood in the open air for a time, but protected from heavy storms of either wind or rain; but early in the autumn they should be removed indoors, where they will soon begin to display their charms, continuing all through the winter and spring. I should be glad indeed to see these and other Australian plants again become fashionable. The following are a few of the most commonly grown; but they are plants that readily cross-breed, and, therefore, new and fresh varieties may be easily obtained. *C. alba*: This is a somewhat small-flowered, white kind, which should always be kept in stock, as it is the best and freest-rooting, and should be used as a stock. *C. brilliant*: A fine habit, and large flowers of a rich bright-crimson. *C. cardinalis*: An abundant bloomer, but somewhat lax in its habit of growth, requiring some care in its pruning; flowers large, bright-scarlet, tipped with green. *C. Harrisii*: A plant of good habit of growth, and free in blooming; flowers of a vivid-scarlet. *C. pulchella*: As its name implies, this is a very pretty kind, being compact in habit, and its bright-scarlet blooms are freely produced. *C. magnifica*: This is a robust, free-growing kind; it produces the large white flowers in abundance.

Out-flowers of "Geraniums" or Zonal Pelargoniums.

forcing or hastening the blooming period of many kinds of flowers, but also in retarding others, so as to concentrate a large supply on a given date. The following kinds are well suited to the purpose—viz.,

AZALEA INDICA, in many varieties, are plants that naturally bloom at an early period of the year, and therefore require very little artificial heat to have them at their best for Easter. The old *A. indica alba* is a grand variety, but for pretty little plants, with fine semi-double blooms, having large round petals of the purest white, there are none to surpass *Dautsche Perle*.

CHOISYA TERNAUTA (the Mexican Orange-flower) is a beautiful evergreen shrub that on open walls in the South of England blooms very early; but it is liable to have the purity of its lovely blossoms spoilt by late spring frost. For this reason I find it best to plant it as a wall climber in the back walks of vineries or any glass-house, where it will produce a splendid crop of bloom in spring.

CALLA (RICHARDIA) ETHIOPICA is essentially a spring-flowering plant, and at no period of the year are such quantities of bloom seen in the market as at Easter. Single crowns grown in medium-sized pots and kept in an intermediate temperature will flower splendidly, and may be hastened on or retarded at pleasure.

if placed under the stages, lifting them up close to the glass when the bloom-spikes push up.

LILIUM LONGIFLORUM and *L. Harrisii* are splendid plants for Easter decorations. Good strong bulbs should be procured in September, and potted singly in 5-inch or 6-inch pots, setting them in a cool frame, and keeping moderately dry until they start to grow, when they may be transferred to a shelf near the glass, in a temperature of about 50 degs. Keep a sharp look-out for green and black fly, as they soon spoil the purity of the bloom.

NARCISUS of all the white kinds, if kept in a cool house, will be at their best for Easter. The double kinds are especially good.

PELARGONIUMS, Single and Double Whites, have been greatly improved of late, and having finely formed massive blooms, are very effective in floral decorations (see cut). *Queen of Whites* is probably the best of all Singles. A dry, moderately-warm atmosphere to keep the blooms from damping is the thing to aim at.

ROSES need only very gentle forcing to have them in bloom at Easter—in fact, a cold-house, if facing south, will usually hasten them enough. There are none to excel *Niphetos*, of which there are two distinct varieties, the climbing one being excellent for training on wires, close to the glass, and the older dwarf variety for pots.

STYLIS VARONICA, certainly one of the most

C. speciosa: This is also a good free grower and flowerer, but its tubular flowers are erect and bright-red. *C. vaustrica* is a slender grower, but bushy in habit; the flowers are large, bright reddish-crimson, with the tips green. J. J.

HOUSE & WINDOW GARDENING.

PLANTS FOR WINDOWS AND ROOMS.

The spring season is at hand, when those who wish to keep their windows and rooms bright with plants will think of purchasing the most suitable things. I will point out a few plants that will live under such conditions, and by keeping to this selection much disappointment may be prevented. The fault is in buying from street hawkers little Orange-trees and exotic plants that are "made to sell" by being placed in strong heat to promote quick and apparently vigorous growth. But unfortunately it is this type of plant that when placed in a room or window, the temperature, of course, being much lower, soon presents a very woe-begone aspect. In a week scarcely a leaf remains, money is wasted, and sometimes plant-growing is given up as a troublesome, expensive, and disappointing pursuit. The true reason, however, is that an improper selection has been made, as there are several plants that will thrive in windows and rooms almost as well as in a plant-house. Where dust and dirt are less prevalent

This **INDIA-RUBBER-PLANT** (*Ficus elastica*) is one of the most popular things to grow in rooms, and when brought from a street barrow or shop care must be taken that at the commencement the plants are not exposed to cold draughts. Most probably they have been heated in a high temperature, and feel acutely the sudden change from strong heat to cold. The glossy, rich green-leaved examples one sees are nearly always thus treated before being sold, and they are lacking in hardiness and strength. As the India-rubber-plant is excellent for rooms, it is very easy to first place the plants in the warmest rooms of the house, so as to gradually inure them to their altered conditions. Always water with care, more mischievous results from improper watering than many are led to think, the soil being always kept moderately moist and no more. Also sponge the leaves occasionally to remove impurities from the surface, as in rooms, especially near large towns, they quickly get covered with dust and dirt. It will not be often necessary to repot the plants, as with careful attention in watering they will last a long time without need of disturbing the roots. An excellent soil when potting is needed is one made up of loam and peat, four parts of the former to two of the latter, with sufficient sharp silver-sand to render the whole fairly porous. Two or three clean crocks in the bottom of the pots will suffice for drainage.

ASPIDISTRA LURIDA and its variegated variety are the two best window room plants one can have. The variegated variety is the brighter in appearance, its broad leathery leaves being finely marked with cream colour. A well variegated example is as choicest as a flower. Under the most unpleasant conditions for plant life the *Aspidistra* will thrive, the great point being to give water judiciously, and keep the leaves carefully sponged. Sometimes the variegation on the variegated form departs, when the plants are grown in the shade, and, therefore, if the position is dark, select the green-leaved type. Even in shop-windows in London this Japanese plant will thrive with vigour. Ordinary heavy soil suffices, and constant repotting is unnecessary. The plant is of slow growth, and fine specimens are expensive, each leaf as a rule being valued at one shilling. On the Continent, where the *Aspidistras* are grown in great numbers, the price of the plant depends upon the foliage, this being reckoned at a franc each leaf. If only one plant is selected for the room or window it should be this *Aspidistra*.

ACACIA LOPHANTHA does not look much like a good plant for rooms, but it is excellent for this purpose, the beautiful feathery foliage and yellow flowers appearing to distinct advantage, even in rooms lighted by gas. When young pinch back the shoots occasionally to prevent the plants growing too tall, and always maintain the soil in moist condition. When in full bloom it is most attractive. The graceful *Cyperus alternifolius* and its variegated variety will live for years in rooms, and grow in a plant-pot

age. The growth is very graceful; and when placed in a bowl an excellent adornment for a room is gained. A large healthy specimen of *Cyperus* is of much beauty, and as it delights in moisture, this is one of the main requisites. If allowed to become dry, the growth soon gets unhealthy. It may be in the summer months almost stood in a bowl of water. A very useful plant for windows is the

AFRICAN ALOE, of which there is a very attractive variegated variety. The firm leathery leaves kept clean by occasional spongings of water, and if the latter kind is used sun is necessary to preserve the distinctive variegation. When potting make the soil firm, and ensure good drainage by providing plenty of crocks.

CORYPBA AUSTRALIS makes a good window Palm, and the same precautions must be taken as advised for the India-rubber-plant. Keep the leaves sponged well, and the soil not too wet. These are a few of the more useful house and window plants, because they invariably do well if reasonably attended to. *Pteris tremula*, and *P. cretica*, both the type and its variegated form, may also be made note of, and of flowering plants outside the usual things, such as *Pelargoniums*. One has a treasury of good window-subjects in the Bell-flowers (*Campanulas*), especially *Campanula isophylla*, *C. carpatica*, and *C. muralis*. In many country towns the windows are made gay with these in hanging-baskets throughout the summer. They bloom with such profusion that often almost every leaf is hidden. C. T.

3275.—Flowers for a hall in winter.

—Yellow Winter Jasmine would not open its buds well in a hall, where there is usually but very little direct sunshine. It is a hardy climbing shrub, and grows best on the wall of a house; it might possibly be grown out-of-doors in a pot, but would not bloom freely in that way. A Myrtle (which, however, flowers in summer) might stand for a short time without injury in a hall in winter, and the evergreen foliage would be suitable; but if gas be burned in the hall, or the plant is too long without sunshine, it will become shabby and drop its leaves. Christmas Roses, grown in a large pot or a small tub, will also stand for a short time in a hall in winter without injury, but the buds would soon cease to open, and if the plant should be kept in a hall more than three or four days it will be completely checked. Palms are the best plants for hall decoration, and a few other foliage plants, such as the India-rubber-plant (*Ficus elastica*), and the Parlour Palm (*Aspidistra lurida*), both of which are very long suffering in the matter of semi-darkness and cold draughts, both of which are ruinous to all flowering plants, and to delicate Ferns. The best Palms for this position are the following: *Corypba australis* (the Cabbege Palm), *Phoenix dactylifera* (the Date Palm), *Scaevola elegans* (the Bungalow Palm), *Chamserops excelsa* (the Fan Palm), and *Chamserops humilis* (dwarf Fan Palm). The lovely Australian Silky Oak (*Grevillea robusta*), too, will stand for some time in a hall, if well established. Any of these plants can be procured in summer (avoiding specimens which have been forced for spring work), and thoroughly though gradually hardened out-of-doors. They may then be placed in the hall for the winter, and will only need regular watering and to have their leaves kept free from dust by sponging them every week.—I. L. R.

3206.—Ornamenting a parapet.

—Large seed-pans, well-drained and filled with a good compost, would do on the top of these pillars, and it might be possible to place a handsome pot-plant in the centre of each seed-pan, so as to get height for the middle plant. *Mimulus* and *Violas*, both of which will grow well without much sunshine, might be planted round the seed-pans, choosing strong plants well set with buds, and planting them in April. *Lobelia* (blue) and *Yellow Moneywort* might also be tried if the pillars are far enough from the house to get direct vertical sunshine; they will bloom in good soil. Mother of Millions (*Saxifraga tomentosa*) would make a beautiful trailer, and do well without much sun; this and the *Lobelia* should not be put out-of-doors till all fear of frost is over.—E. C. About the end of May. *Nasturtium* (the Tom Thumb varieties), especially those with dark-bronzy foliage and ornamental blossoms, would look well; they should not,

however, have rich soil, or they will get too much to leaf. For the central pot, which should be sunk half-way in the seed-pan, nothing will be better than well-grown old plants of *Zonal Pelargonium* ("Geranium") of a good variety, which have been brought on in a sunny place or window until they are covered with bud or bloom, at the end of May. They will go on blooming for some weeks, and should then be replaced by a second set of pot-plants (Yellow *Calceolarias* will do well in the shade), and again set in full sunshine to form a fresh set of buds, being top-dressed with good soil at the same time. In this way a constant succession of flowers may be had through the summer even in a north aspect, using a south window on the other side of the house to bring the plants on.—L. R.

Iris Bakeriana.—This is a charming bulbous Iris, which may be grown in the open, in a pot for the greenhouse, or in a window-box. It has not been long introduced from Asia Minor, and is a relative of the well-known *I. reticulata*. It is free in growth, and the flowers are Violet-scented and richly coloured. They differ in one important particular from those of *I. reticulata*, in the lip or fall; the three lower segments of the flower are blotched with white, on which appear violet spots, differing in size in individuals. In some cases they are practically absent, and again the flowers are enriched with yellow in some individuals, whilst the violet margin to the fall varies in width. When out-of-doors the flowers should be protected in some way from the weather, otherwise they will suffer considerably. A warm, moderately light soil is best. Early in the year its flowers are most welcome, and it is not difficult to get the bulbs to bloom then with an ordinary greenhouse.—V. C.

3318.—Dissolving bones.—Place the bones in an earthen vessel. Mix one part of sulphuric acid with two parts of bones in weight. The acid should be diluted with its own weight of water. Stir the mixture occasionally for two or three days. When the bones are thoroughly dissolved add about thirty times their weight of water and use. When the mixture is made on a large scale the bones may be laid in a heap on a hard floor, and the acid and water poured over them, and the product afterwards placed in a tub for further dilution or to make into liquid-manure.—E. H.

3341.—A plague of Sparrows.—Keep a tame Hawk in your garden, or scatter some Oats on a small patch of ground prepared with hair-springs or limed twigs. Whatever you do, do not use poison, or you will destroy your friends as well as your enemies. To protect any special plants, black cotton stretched backwards and forwards just above or at the side of them is very efficacious, as the birds catch their legs against the thread, and are alarmed thereby.—A. G. BUTLER.

3331.—Lavatera arborea variegata.—These are very easily raised from seed in hot, and if not overpotted they soon get their true colour; therefore it becomes a question, where there is a command of heat, if it is worth while keeping leggy plants. If it is decided to keep them, cut the plants down near the bottom, and use the tops as cuttings. The roots, if healthy, will also probably throw out shoots from the base. The tops will strike best if the ends are inserted in a bed of warm, moist Coco-nut-fibre, and potted up as soon as roots form.—E. H.

—No doubt these plants will bear cutting down moderately if you keep the roots rather dry for two or three weeks afterwards; but I do not think the tops will form roots if put in as cuttings. Certainly, I would not throw the plants away, as if you plant them out in a rather poor soil, and where they get plenty of sun, they will make fine specimens during the summer. This *Lavatera* is also useful for large bouquets if it is given a rather large pot, and gets plenty of sun and air. The variegation is very clear and bright in the open air, but it is better under glass.—J. C. C.

3315.—Culture of Nertera depressa.—*Nertera depressa* (Fruiting Duckweed) is not difficult to grow. It is generally worked on in heat in spring; the intermediate-house, 56 days at night, will suit it till the flowers show. Then move to an airy greenhouse to set the flowers, as the seeds ripen chiefly in the fruit. In May move to a cold frame, and when hardened off plant out. It is mostly used as a cover plant in carpet bedding.—E. H.

ORCHIDS.

CATTLEYA TRIANÆ.

I AM asked by "James Martin" to give him some idea about how he should treat this plant; also to state if I think this a distinct variety? He has just got a box of them sent home by a friend, and he would like to grow them. Well, respecting the specific distinction, I must give an adverse opinion, because I look upon Trianæ, Mossie, Mendeli, giga, speciosissima, and others, as only forms of *C. labiata*, which was named by Lindley upon its first introduction, and has only been recently reintroduced to general cultivation by Mr. Sander, of St. Albans. These various *Cattleyas*, although they do possess evident distinctions in their flowers and in their time of flowering, yet they do not appear to give any proofs otherwise than that they are varietal distinctions, which have been brought about by climatic influence

of the roots; but depend upon it, the root rotting is caused by too large a quantity of water being given to the plant, and this frequently not well drained away, and that is the reason why Orchids require so much attention in the matter of drainage, because the water should pass rapidly away. *Cattleyas*, however, differ considerably under cultivation to the majority of Orchids, as they do not require much water. The roots should have just enough to keep them in a moist condition, and if they get more they will show signs of going wrong, and a great deal of water may be used in damping down the house, on the stages, and between the pots; but the roots should never have any given them unless they are really dry, and at the same time the water supply should quickly be carried away. Do not put these plants on blocks of wood, for although they will grow and thrive on these with proper attention, I do not like the plan. Therefore, I say, do not start them on blocks of wood, and whenever they

condemned, and for years we have really seen nothing of them in English gardens. On the Continent, however, these plants have been better looked after, and there I have seen from time to time many kinds flowering. I was also greatly pleased to see an order for one in a nurseryman's hands the other day, and also that he had a plant which he could supply, and on the same day a letter came from "Judy" asking for information about *S. tigrinum*. It was quite right to transfer it from a pot to a basket, as the flowers of all these plants are produced in a downward direction. There is no chance for them to be seen if grown in pots; but I prefer wire baskets to wooden ones, because these are plants which do not like to be disturbed, and the wooden baskets come to grief sooner than wire ones, and require renewal; but for that matter, if the plants grow out and over the sides of the basket, be it of wire or wood, they will not require another, or there is no necessity to replace with another, saving for appearance sake, and I may say that I grew for some years quite a collection of these plants without any receptacle at all, but simply ran a stout wire down through the bulb and fastened it below. This plan, too, I am persuaded, is more conducive to the production of flowers than putting them into baskets and surrounding them with a mass of soil. These plants are of easy culture, requiring to be hung up in the shade, where the leaves keep of a good colour and the plants grow freely. During the period of growth the plants should have a very liberal supply of water, both to their roots and overhead from the syringe; but during the resting season a period of dryness may be given with good results. They grow best in the heat of the *Cattleya* house, but during their rest they may be kept cooler. The soil should be a mixture of peat and Sphagnum Moss, but do not overload them with soil. The following are a few of the kinds which I have grown, but as their leaves and bulbs are very similar, they are not mentioned separately. Suffice it to say, they are strongly ribbed, tough, and somewhat leathery in texture, and evergreen. *S. Bucophalmis*: Flowers large, tawny-yellow, spotted and blotched, deep-blood colour. They emit a powerful aromatic odour, which, however, is not overpowering if the house is properly ventilated. It blooms during late summer and autumn. *S. Devoniensis*: Flowers produced in pairs, creamy-yellow, profusely spotted with deep-purple or crimson, lip creamy-white, having a deep stain of purple, besides being spotted with the same colour. It is very delicately perfumed, and it blooms during the late summer. *S. ebernea*: This is a very fragrant kind, which blooms during the summer months. The flowers are ivory-white, having the lip sometimes stained with dull purple. It is amongst the most rare of the kinds. *S. grandiflora*: This is another rare kind. The flowers are gratefully perfumed, and pure ivory-white, sparingly spotted with light crimson. It blooms usually about the end of the summer months. *S. insignis*: A beautiful and pleasing flower and very sweet-scented, the ground colour is creamy-white, being abundantly spotted with purple, the lip, in addition, being shaded with deep-purple. It blooms during the autumn. *S. Martianum*: This plant mostly produces its large flowers in pairs, having its large straw-coloured sepals dotted with reddish-brown, and the pure-white petals, which are much smaller, having a large blotch of crimson at their base, the upper portion being spotted and dotted with the same colour; lip white, stained at the base with dull crimson, and the thick column dotted with purplish-crimson. It flowers during the autumn, but I cannot speak favourably of its odour. *S. oculata* produces a many-flowered raceme, which is agreeably scented. The ground colour is soft lemon-yellow, profusely dotted with rosy-lilac, the lip white, having on each side a large eye-like spot of brownish-purple. It blooms very freely during summer and autumn, the varieties being numerous. *S. ornatisima*: This bears exceedingly handsome flowers, and they are freely produced, the ground colour of the sepals and petals being orange, blotched at the base with dark-crimson maroon, and spotted with red in the upper parts; lip creamy-white dotted with rose; it is very agreeably perfumed, blooming late in summer. *S. radiosa* has somewhat small flowers, sweetly scented, they are suffused with

Flower of *Cattleya Trianæ*.

and position. Nevertheless, they retain their peculiarities and their markings, some few plants edging off at times into another form; but for all purposes of a garden plant the present *Cattleya* may be considered a distinct kind, and exquisitely beautiful. To grow this Orchid in a proper manner, first, all the plant must be trimmed of all the dead rubbish that is about it, taking care that the eyes or young growths are not injured, for now these will begin to become prominent, and the whole plant should be washed in lukewarm soap and water, which is a precaution often overlooked by the trade growers; but I always like (in a private place to see plants look smart and clean, and in observing this rule one often gets rid of some colony of peats, which would otherwise become a great source of annoyance. The plants should be placed in somewhat small, well-drained pots, using for soil a mixture of good peat-fibre and chopped Sphagnum Moss; for this latter I am a strong advocate, notwithstanding having heard such a long list of the evils it produces. Amongst the worst of these comes the rotting

are started, remember not to overload them with soil. The plants at this time of the year may be kept in a temperature not exceeding 65 degs., falling 5 degs. or more during the night; but later on in the season it may range up to 85 degs. with sun-heat, and at all times let there be a free circulation of air. I do not see why the plants should be compelled to live half their time with the fresh air excluded; they certainly are not so treated in a state of nature, and above everything, I say, avoid overwatering. Now I think my young friend, "J. M.," should succeed with his *Cattleyas*. If there is any other point not touched upon I should like again to hear from him. MATT. BRAMBLE.

STANHOPEAS.

I AM very glad to find these plants are again being taken into favour. When I was a boy Stanhopeas were largely grown, and their highly-scented flowers became quite a nuisance in the house; then came the fact that the flowers did not last long, and they were

lemon-yellow more or less spotted with crimson, the lip and basal part of the flowers brownish-orange; it blooms in the summer months. *S. tigrina* is a grand species, bearing its very large flowers in pairs mostly, but sometimes three or four are produced on the same raceme; they are very strongly scented, and are of a rich buff yellow, heavily suffused with deep portwine colour; it blooms in the late summer and autumn months, and is the largest kind that I know. *S. Wardi*: This plant must be reckoned amongst the most handsome, and it is very free in blooming. I have flowered plants with five and seven flowers on a raceme, the colour being rich golden-yellow, more or less dotted with purplish-crimson, and at the base of the lip is a deep velvety blotch. These and some others I have grown, and I hope "Judy" will grow them well also. If she keeps her house properly ventilated they will be a great source of enjoyment to her.

MATT. BRAMBLE.

3300. — *Funkia subcordata grandiflora*.—This is the proper name of the variety to which "Black Bess" refers. There is no variety of subcordata under that name, but this kind is a fine species, and a native of Japan. It is so pure and sweet in blossom, and so lovely withal that a well-grown pot of it is hardly inferior to a pot of *Eucharis amazonia*, with this advantage, that it is more generally within the reach of all who wish to have it. I have no doubt that "Black Bess" has the plant true to the above name, and let me say on the special difficulty attaches to its culture either out-of-doors or in pots. If so many gardeners have failed with it in the case mentioned it must be because they did not do all that might have been done. In a previous situation I had a great quantity of this plant. At first all was outside, there being several groups upon a border of Bamboos growing in partial shade to sandy loam. The peculiarity of this species is that it flowers in late summer and usually too late to open in perfection. I had the satisfaction of seeing an abundance of spikes appear in September, but not one flower in twenty opened to perfection before autumn rains and early frosts destroyed them. I was advised to plant some plants if possible on a mound of sandy loam in an open sunny spot to encourage early flowering, and this was done with success. If "Black Bess" plants has small leaves it is evidently under some unfavourable influence. Soil may be too heavy, and wet or dry, or impoverished with roots of other things running through the ground. I also potted some up. They were given good sandy loam, and grew to so ordinary greenhouse. They produce magnificent leaves and fine flowers, which opened to perfection and lasted well. The flowers have a delicious fragrance. I think if "Black Bess" trees, success will be achieved, and though it is a hardy plant it merits all the trouble that might be bestowed upon it, and repay the cultivator in proportion to the care he takes of it.—A. H.

3327. — *Pig-manne in the garden*.—This manure is excellent for all kinds of vegetable crops, and if used at the time of planting should be in a decayed state. The best way to use it is to dig it in when the weather is fine in the autumn wherever ground is ready for it. All the Cabbage tribe revel in it.—J. D. E.

— This is very good manure on light land. If used at the time of planting it should be thoroughly blended with the soil, and not come in direct contact with the roots of anything.—E. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experiences is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

3369.—*Aranaria imbricata*.—What is the best method of raising this from seed?—I. R. W.

3370.—*Onions for show*.—Will someone kindly give me a few hints on the culture of Onions for show?—J. W.

3371.—*Cinders and ashes*.—Are these injurious to coniferous trees, and Evergreens if dug in near them?—L. H. C.

3372.—*Roses on Briar cuttings*.—Will someone kindly tell me how to grow Roses on Briar cuttings?—SYLVANUS.

3373.—*Sweet and Savoury Herbs*.—Will someone give me the list, &c. 1, the Sweet Herbs generally in use; 2, the Savoury Herbs?—M. H.

3374.—*Parsley in winter*.—Will anyone kindly say what is the best method to adopt to secure a constant supply of Parsley during winter?—I. B.

3375.—*Potato disease*.—I have been told that sulphate of copper will stop disease in Potatoes. Will someone kindly tell me how to use it?—CARRIS.

3376.—*Manure for Roses, &c.*—Where obtain manure cannot be got, what kind is the best to use for Rose-trees and flowers generally?—MRS. BROWN.

3377.—*Treatment of Carnations*.—How can I get Carnations to have a strong, sturdy stem? Mine always being their heads and look straggly.—REVISED.

3378.—*Chrysanthemum "Cyclone"*.—Will "E. M." be kind enough to tell me what kind of Chrysanthemum is Cyclone, as I cannot see its name in any catalogue?—G. A.

3379.—*Violets and Lilies of the Valley*.—When is the time to plant these, and what are the best kinds for planting in the open air without protection in the winter?—MRS. BROWN.

3380.—*Ants*.—Ants are troublesome in my stove-house. Is there anything I can do over the pots or the mould which would stop their getting on to the plants, and not hurt the latter?—ENQUIRER.

3381.—*Creeper for a chalk bank*.—Will someone kindly give me information as to what creeper would answer best to cover a bare chalk bank? Would *Nasturtium* be likely to grow?—M. A.

3382.—*Treatment of Anemone Mollis*.—I shall feel obliged for directions how to treat *Anemone Mollis* after flowering—viz., should the shoots be cut back to 3 inches or 4 inches and then be planted out?—BARKER.

3383.—*Sulphuric acid and weeds*.—Some time ago I saw it stated that a solution of sulphuric acid in water would destroy weeds on a path. Will someone kindly give me the proportions to use?—PRINCESS.

3384.—*Tarring wood*.—I want to tar some wood borders in my garden. What can I mix with it so that it will dry in properly, and not to come off on one's hands or clothes on being touched afterwards?—ENQUIRER.

3385.—*Treatment of Spiraea japonica*.—Will anyone tell me how to treat *Spiraea japonica* after flowering? Should they have any water, or be allowed to die down at once, or should they be put out-of-doors?—BEGINNER.

3386.—*Vegetables for show*.—Will someone kindly tell me what would be the best vegetables to show in a collection, limited to eight varieties, the last week in July? I can grow well Tomatoes and Cucumbers.—MILL VIEW.

3387.—*Violets for outdoor culture*.—What are the best Violets for outdoor culture, and when should they be planted? Can I increase my Violets by subdividing my plants, or do they increase more by being left undisturbed?—CAROLINE A. OATES.

3388.—*Rose diseases*.—I should be obliged if someone will kindly tell me the cause of, and, if possible, the cure for, the brown patch which surrounds the stems of Roses, killing the bark and, of course, that part of the shoot above it?—A. SPENCER.

3389.—*Budding or grafting Ash trees*.—I have two Ash-trees I want to bud or graft with weeping cortex. Which would be the best way? They are each about 5 feet high, and have four branches to each top about the size of a man's finger.—W. G., Essex.

3390.—*Choice Primulas for show*.—My employer tells me that a friend of his who exhibits Chinese Primulas successfully does not show them the first season of flowering, but selects the best plants and shows them next year. He wants me to save some plants now in bloom and prepare them for exhibition by November. Will anyone kindly oblige me with particulars as to how they should be treated? I have always raised fresh plants every year, and, after flowering, thrown them away.—M. J. RSTI.

3391.—*Liquid-manure*.—We small suburban gardeners have not room for a tank to keep this in. Would ordinary bedroom slops, properly diluted, do as an efficient substitute? I think many hundreds of readers would be glad to know also.—LENSARD.

3392.—*Pheledium anreum*.—My plants looking very bad, and I found there were wireworms in the pot. I watered it with lime, and then repotted it with peat, good mould, and silver-sand. Ought I to cut it down to allow it to shoot again?—MISS M. CURMING.

3393.—*Cyperus alternifolius variegatus*.—I have lost several plants of this, notwithstanding I kept them in a stove temperature and well watered and with good drainage. The foliage turns brown and dies away. Can anyone account for it?—ENQUIRER.

3394.—*Culture of Pelargonium*.—Would anyone kindly inform me as to culture of Pelargoniums? I have got some fine plants of Regalis, and they are not doing well. Full directions needed as to culture and training for show purposes?—JOHN COWIE.

3395.—*Azaleas after flowering*.—Will anyone give me some information about Azaleas after flowering? Do they require any pruning, and should they be put out-of-doors in summer in North Yorkshire, or kept in the coolest part of the greenhouse?—BRINKER.

3396.—*Rose in a greenhouse*.—I have a Rose in my greenhouse, and am told that I must let the young wood grow close against the glass. Is this right? If so, how am I to get it below the wires next winter? I am also afraid the leaves will get scalded?—ANXIOUS.

3397.—*Orchids and Cacti*.—Will someone kindly give me the names of a few strong Orchids (not expensive ones) suitable for growing to a small glass-house devoted to Cacti, where, of course, the temperature is very high in the summer-time, and a minimum of 50 degs. in the winter?—CACTUS.

3398.—*Grapes in a lean-to house*.—Can I get a good crop of the best in a lean-to house, by 12 feet, facing due east, and getting the morning sunshine unintercepted? Angle of roof, 45 degs. In heating will ordinary water pipes and cement joints do, or are expansion joints indispensable?—JESSEMAN.

3399.—*Work in orchard-house, &c.*—I should be obliged if anyone will be good enough to say what sized orchard-houses and hot-houses a man might be expected to work single handed, when required to do nothing else, save occasionally to advise as to other parts of garden?—SUBSCRIBER X.

3400.—*Black Raspberries*.—I have several American Black Raspberries. They grow differently from the English, and do not appear to seed up shoots from the roots, and the roots do not spread. How can I propagate them? Would slips or cuttings strike, and when should they be put out?—BLACKBERRY.

3401.—*Sowing Grass seed*.—I intend sowing Grass seed to renovate my tennis-lawn next week, and should wish to know if, after the seed is sown, I may still continue to roll the lawn with a light roller, as I do not know whether the roller is injurious or beneficial to the tender blades of Grass?—LAWN MOWER.

3402.—*Beds on a small lawn*.—I have three flower-beds on a small lawn, which I want to look gay this summer, but they are shaded. I should like to know which will be best to plant them with, as they are just in front of my dining and drawing-rooms. Any information will greatly oblige.—MID HURON.

3403.—*Rose "Her Majesty"*.—I have had a Rose "Her Majesty" for two or three years, which has only once had one bloom on it, and is frequently covered with mildew. Is there anything I can do to make it flower and be more healthy? I syringe it frequently with paraffin oil and soap, but with no effect.—REVEREND.

3404.—*Asparagus plumosus*.—Will anyone kindly tell me the best, quickest, and cheapest way to work up a stock of this for cutting purposes, by seed or by cuttings, and the best method by carrying out the same? I have the *Asparagus plumosus nanus* any advantage over the larger sort for cutting purposes?—A. BUSCAIEN.

3405.—*Salting an Asparagus-bed*.—I should be much obliged if someone will let me know if it would do to sprinkle salt over an Asparagus-bed that has only just been planted, so soon as the heads begin to show themselves through the surface of the soil, as I believe Asparagus likes salt, and it is destructive to insects and weeds?—W. K. B.

3406.—*Gloxinia seedlings*.—I have some late Gloxinia seedlings of last year, which have been growing all the winter, and are now about 3 inches high, in small pots. How should they be treated? What soil, position, and temperature do they require? Do they want much water, and what sized pots should they have for flowering?—JOKRAMUS.

3407.—*American Blackberries*.—Will anyone who has been successful with the American Blackberries kindly favour me with cultural directions? What pruning do they require in order to fruit well? I have grown one up the front of a house, which it has covered. The aspect is south. Should I leave it as it is or prune it? I do not get much fruit.—BLACKBERRIES.

3408.—*Plants for a flower-box*.—I have a flower-box over the porch of my front door. I have arranged for a Clematis on each side of the trellis, and think some pretty flowering trailing plant would be suitable for the box. Will someone kindly recommend me something to answer my purpose, as I want to have something nicer than *Nasturtium* or *Caery Creepers*?—J. GORDON.

3409.—*Names of Chrysanthemums*.—I should feel obliged to "E. M." for the names of ten dozen Chrysanthemums, divided as follows: One dozen of the largest blooming varieties, named separately; one dozen Japanese reflexed; and one dozen incurved. These latter two dozen to be such as will produce a fair number of flowers of good colour when grown on the natural stem. As to colour, I should like several good whites and yellows, but I do not care for magenta or shades of magenta. I did from experience there are some few varieties (I forget the names) which, although they receive the same treatment as the rest of the stock, produce nothing but large leaves and stems, and do not flower at all. I should like these excluded, if possible.—MARCUS.

3410.—Christmas Roses—Will anyone tell me if there be any means of preventing some varieties of Christmas Roses dying within a few hours of being poked and put in water? The tall growing greeny-white and rose-colored ones will not last for ten days. It is nearly useless growing some of the varieties for the above reason. Could I put anything in the water?—V. B.

3411.—Arms not flowering—Will someone bid kind enough to advise me what to do to make my Arms flower? I keep them in pots in a small greenhouse. Last year I stood them out during the summer, and out them down; they are green and flourishing now, but do not show any flower-buds. The year before I planted them out in summer and potted them again in autumn, but still they did not blossom. One did flower two years ago, but not since. They are of different ages.—C. H.

3412.—Winter Aconites not flowering—The year before last I planted a considerable number of Winter Aconites in my borders and also in the turf; the next January they flowered well. This year, however, January passed without a sight of them, and when the Snowdrops had been in flower about a week, the leaves of the Aconites showed themselves, but without even a bud. What is the reason of this, and what should I do to have them flowering next year? All the leaves are large and healthy. Locality: London, S. Kensington.—FLORA DE LYA.

3413.—Marchal Niel Rose in a greenhouse.—I have a Marchal Niel Rose growing in a box in a greenhouse, immediately over the heating pipes. It flowered well last year, and had every appearance of doing so this year, as it is literally covered with buds; but within the last week a different complexion has come over it. The buds have ceerily all drooped, and the leaves, instead of having the healthy appearance they had, have now a very withered look, and the younger growths are all shrivelled. I have not the time at night, but there was no frost to talk of. One of the buds that have expanded are very small, and give off an unpleasant smell, and some of the buds are dropping. What shall I do?—O. P.

3414.—A Gloire de Dijon Rose.—Would anyone please to inform me to what I should do with a Gloire de Dijon Rose I have growing in a greenhouse. The roots are planted outside at the end of the greenhouse in a bed made on top of the boiler-flue, and covered with soil. Last year I had some fresh manure placed on top of the bed, thinking to benefit it, but instead, with the frost raised, it told seriously on the health of the Rose. The leaves turned yellow and fell off. After that I cut away all the dead wood, but it has scarcely made any growth, although buds have appeared this year, but when they expand are very small, with scarcely any smell, and covered with green-fly, in spite of frequent fumigations. In the same house are also two Black Hamburg Vines, and a mixed collection of plants.—Rix.

3415.—Double Fuchsias, &c.—Will J. C. C. tell me the reason of my Double Fuchsia of last year coming single this? Mine have done so for years, old plants as well as cuttings. Last year I took a quantity of cuttings, all from double flowers, but find most of the blooms at present are single, and most of the old plants (2 years old) that were double last year, and have flowered this, have come single. I have had plants with some single and some double blossoms on the same stem. I have them repotted every year, and in the best mould. Also can J. C. C. tell me the cause of a little white maggot, about as thick as cotton, and a quarter of an inch long, coming in the mould in pots? They always attack my Herbaceous Calceolarias, and when once they get the plant never grows, but gradually dies. I shook a plant out of the pot the other day that was looking slokly, and found a quantity in the mould and round the roots. They destroyed nearly all my early Cauliflowers from seed sown at Christmas in the greenhouse; they eat all round the stem under the mould just after the young plant comes through the ground, and so makes them drop and die. They also destroyed nearly all my Cactus Dahlia seedlings in the same way. I have been troubled with them for years. Soot has no effect on them.—OLD SUBSCRIBER.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3416.—Orchids from Brazil (July).—When you put them in a moist house, moderately heated, and then let me know what you have got, and I will answer with all possible dispatch.—M. B.

3417.—Zosterostyles arachnites (J. Hmsan).—The specimen you send is undoubtedly of this plant. I received it from Cayton and flowered it some thirty years ago, but I have never seen it since. It appears to also come from Java and some other islands in the Indian Ocean. One species only seems to be recognised. The plant should be potted in a mixture of peat and loam made rather sandy, and it should be kept nearly dry when it is at rest and dormant.—M. B.

3418.—Ottolya Warneri (M. Maxwell).—There really is no reason why this plant should be called the summer-flowering labiate any more than O. Mandall and some others, for all are recognised as belong varieties of labiate. The one that really did have the name of the summer-flowering labiate was what is now known by the better name of O. Gekallusa; but if you object prefer the longer title to the name of O. Warneri, well and good; let him use it. But, since you ask me, I do not think he can find any authority for this title.—M. B.

3419.—Oleandra indivisa.—J. Heron sends me a specimen of this plant, which is an abundant plant in New Zealand, where it clothes and festoons large trees on the outskirts of the forests. It is an admirable plant for a cool conservatory, and it always blooms abundantly at this season of the year. I used to fasten the shrub with its flowers at Easter for many years, and for this purpose they are exquisite. I recently saw the plant flowering freely in quite a small conservatory, but with the complaint of free blooming qualities; but when it is allowed to stand in a room on the roof of a conservatory, it is a sight never to be forgotten. It should be grown by a person who has a convenient place.—J. J.

3420.—Three good flowering Acoacias.—J. Franklin asks for the names of the three most beautiful of this family? I do not say these are the best, but they are very beautiful kinds, and well deserving a place in any garden. A. Drummondii. It has pinnate leaves of a rich green hue, and long cylindrical spikes of bloom of a citron-yellow in colour; it is a Swan River species, and blooms all through the months of March, April, and May. A. pubescens is another very handsome species, with bright-green leaves, and bright-yellow flowers, which are massed at the end of the branches. It flowers through April and May. A. Rocioana grows and flowers freely as a small pot-plant, but is seen in its greatest beauty when trained up the rafter of a greenhouse. It has narrow, dark-green leaves, and forms masses of soft, yellow flowers. It is a Tasmanian plant.—J. J.

3421.—Odontoglossum Cervantesi.—F. H. M sends me two specimens of this species, which have appeared, he says, upon the same plant, but the I much question. I am very pleased to find him so enthusiastic in his love for Orchids, but I am only sorry to find him spending his energies and his time on such wretched forms as these. Were you not to have got such wretched forms from I cannot conceive. No; you should grow the species in its normal form and its variety decorum, not such extreme alpine varieties. Get a plant or two of O. Rosea majus and some others, for you really deserve to have a few flowers worth looking at—some that will please, and give you some return for your situation and care. These flowers are certainly of no value to me. I know your town well, and I am astonished that in such a place you can have been contented.—M. B.

Names of Plants and Fruits.

* Any communications respecting plants or fruits sent in must be accompanied by the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Naming fruit.—Reader who desire our help in naming fruit must bear in mind that several specimens of different stages of color and size of the same kind greatly assist in its determination. We can only undertake to name four varieties at a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—H. S.—Acoacia armata.—P. J. G.—Omphalodes verba.—Reader.—Omphalodes verba.—James Knight.—Oleandra indivisa apparently.—Bodger.—Acoacia Drummondii.—General Hawker.—We regret being unable to name the Desmodium sent, but the flowers were too much shrivelled.—Ernest Bacon.—Specimens dried up and insufficient.—East Grinstead.—It is quite impossible to name Strawberries from the leaves only.—G. R.—Cannot name the Mosses from such poor specimens.—Mrs. B. Fox.—No. 8 is Diomea arcoloida. We should like to hear from you again as to the Orchids and other plants. Cocoon name from specimens sent.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Anxious.—Apply to Mr. J. Groom, Seafield Nurseries, Gosport, Hants.—Mrs. Brown.—Apply to Messrs. Birkenhead, Sale, near Manchester.

BEEES.

SEASONABLE NOTES.

In examining hives in spring to ascertain the condition of brood, it should be remembered that on the death of a queen, and when the Bees have not the requisite means of rearing another, fertile workers will deposit eggs in the cells, but lay their eggs very irregularly, sometimes two or three in one cell and then mixing several cells, whereas the queen lays her eggs in patches, rarely missing a cell. Should, therefore, brood-cells be found dotted about the combs instead of being regularly and compactly placed, queenlessness may be suspected. Only drones are produced from eggs of fertile workers. Should it be observed that but a small quantity of pollen is being carried into a hive, while other colonies are very industrious, it may reasonably be suspected that the hive is queenless, and no time should be lost in examining the hive. It being too early in the season to introduce a fertile queen, the only thing to be done with a queenless colony is to break it up, dividing it amongst strong colonies having fertile queens. It is found that queenless colonies retain their drones in the hive through the winter.

GENERAL MANAGEMENT.—Care should be taken that stocks of Bees do not run short of provisions at this time. Large quantities of food are now being used in the rearing of brood. Where the Bees of some hives are seen flying abroad while the rest of the hives in the apiary are in a state of repose, the former will in all probability be found to be very low in the store department—almost at starvation point, being lured out by hunger in the vain search for food. Any bars of honeycomb preserved from last

season will now be found very valuable to supply to needy stocks. They should be slightly warmed before being introduced into the hive, or the temperature of the hive will be much lowered. All causes of dampness must be removed as soon as discovered, and damp quilts replaced by dry ones. March is the best month in the year for purchasing stocks of Bees. Colonies having stood through the winter, there is, of course, less risk of losing them than there would have been had they been purchased in the autumn. If a stock is in a healthy and prosperous condition, numbers of Bees will be observed on a fine day carrying into the hive large quantities of pollen, which is at this time collected to be used in the rearing of the young Bees. In the early spring the Crocus and the various kinds of Willow yield large quantities of pollen, the colour of which varies according to the kind of flower from which it is gathered. The Bee, foraging in the flowers, becomes powdered with the pollen, which it brushes from its body with its front legs, and collects and kneads into little pellets, and transfers them to the hollow in the hind legs provided for its reception and transportation. Before purchasing a stock of Bees the inside of the hive should be thoroughly examined; in the case of a straw skep this can only be done by inverting it, after having blown some smoke into the entrance to clear the floor-board of Bees and drive them up amongst the combs. The combs can then be gently pressed apart and the condition of each carefully noted. They should be built straight and be free from damp or mould, and contain six or seven seams of Bees forming the cluster. The sealed honey will be found in the top of the combs and should be 2 inches or 3 inches deep, while sealed brood-cells should be found in patches on the central combs. Stocks of Bees should be removed in the evening or early morning if in straw skeps; the skeps may be carried in an inverted position with a piece of coarse-cloth tied over, and for better security to combs a pointed stick may be passed through the sides of the skep so as to pierce each comb. If this is done a day or two before removal the Bees will secure the combs to the stick and make all safe for moving.

DYSENTERY.—This disease is caused through dampness inside the hive, and also by the pertaking of unsuitable food by the Bees, such as unripe or fermented honey. An undue consumption of food and excitement in the hive, brought about by the disturbance of the Bees through unnecessary manipulation during cold weather, will also tend to encourage this complaint. Hives found to be foul from dysenteric discharges should have the combs and Bees transferred to fresh clean ones, all soiled frames being scraped and washed over with a weak solution of carbolic. The Bees should be supplied with a cake of candy, a comb or two of sealed stores, or a very good food made by mixing liquid honey and finely powdered loaf sugar together to the consistency of putty. This can be laid upon the frames in the form of a cake, and is readily taken by the Bees. It can be introduced at the feed-hole in the case of straw skeps. The hive should also be protected well from cold and damp, and the Bees disturbed as little as possible. S. S. G., Parkton.

POULTRY & RABBITS.

QUERIES.

3422.—Chloekens and an Incubator.—I should be pleased if anyone would give me some particulars of breeding chloekens in an incubator, the cost of it, and how heated? I propose having a large room, well heated, to place the chickens in when hatched, but suppose the incubator would have to be placed in another compartment? Any other particulars would be most acceptable.—LENO.

3423.—Chickens dying.—Will someone kindly tell me if the seeds of the Laburnum-tree is poisonous for chickens, as I have had several mope and die in a short time after being put near to the Laburnum-tree?—S. R. S.

3424.—Blood in the yolk of eggs.—Will "Doubting" or some other correspondent kindly tell me why the yolk of my Black Moorcock hens' eggs sometimes contain blood? They are pullets of last spring's hatching, seem very healthy, and have laid well since November.—MRS. PAYNE.

REPLY.

3420.—A poultry-house.—The best description of poultry-house is one which fits into any corner of the premises which happens to be at liberty. In other words, no hard-and-fast

rule can be laid down, but sometimes one kind or at other times another will prove the most serviceable. A fowl-house is intended principally for housing the stock at night, and should contain from 8 inches to a foot of perch-room for each adult bird which roosts in it. The perches should be a yard apart at least, and be all of the same height. This will give plenty of room, and there will be no fighting for the best places. "Beginner" can work out the dimensions for himself from the above figures. He must bear in mind that a small house is unhealthy for the fowls and inconvenient for those who have to attend to them; it is, therefore, much the best plan to err on the right side. Attached to the roosting-place should be a lean-to shelter under which the birds can rest during the day. It is best on the south side, and as to secure all the possible sunshine at mid-winter. In this shelter the resting-places may be arranged; fowls dislike to enter a roosting-place for this purpose. So much for the house, &c., for the adult stock. Chickens are best provided with a residence for themselves. A house 6 feet by 4 feet, if well ventilated at the gables, will accommodate twenty-five birds fit for killing. A wooden floor can be put in or not, according to the taste of the owner. A run for twenty-six adult fowls may measure some 26 yards by 12 yards, and as much larger as one likes. It is scarcely fair to pass an opinion on the merits of advertised poultry-houses; but "Beginner" may rest assured that movable wooden houses will answer very well in this country if made stout enough at first and covered with felt in exposed situations. Sometimes they are really too warm when thus protected. I have never found them colder or difficult to keep wholesome and clean; of course the crevices are more numerous than in a brick or stone built house which has been plastered, but when whitewashing is resorted to once or twice a year, and disinfectants are used now and then, the place is really cleaner than most permanent structures. I am in favour of these movable houses, as they enable one to use fresh ground at pleasure and keep the fowls from the garden and the back door.—DOULTON.

BISMARCK.—Grand new Apple, immense pyriform, high-coloured fruit. Bristles freely on very young trees. 2s. each; 18s. doz. Bosty of Bath: Delicious and very pretty early fruit, 1s. 3d. each; 12s. doz.—WILL TAYLER, Nurseries, Bournemouth.

RARE BLUE EVER PEA.—Two, 1s. 8d.; 1 doz., 1s. 6d.; 12 doz., 12s. 6d. Periwinkle, Polyanthus, Aquilegia, 3s. 1s. 8d. free.—MR. LAKE, Brixham, Blandford.

CHEAP PLANTS.—Single or Double Fuchsias, Yellow or White Marigolds, Begonias, and best varieties Chrysanthemums, named 1s. dozen; 5s. 100. Primrose and Violet roots, 1s. 3d. 100; 5s. 500; 1s. 1,000. Delivered. W. H. LAMBERT, Seedling, Blandford.

BEGONIAS.—Unequalled Begonias, selected from very finest strains, fit to grow for exhibition, mixed colours, singles, 4s. per dozen; 25s. per 100. Double 7s. 6d. per dozen; 50s. per 100.—GARDENERS' SUPPLY CO., 77, Rath-street, Birmingham.

SEEDS.—Island, Shirley, Mikado, Swan, Hird, Menisto, Danabrog Poppy, St. Bridgid Anemone, Ecolord's Sweet Pea, 2d. pkt., 5s. 1s. 100. Island Poppies, St. Bridgid Anemone, 3s. 1s. 100. Victoria, Egginton, Leighton Buzzard.

DEVONSHIRE FERNS.—40 rare roots, 16d.; 100, 1s. 10s. 100 sorts: Maiden-hair, Polystichum, Ceterach Adiantum, &c.—H. ANDREWS, Blandford, Dorset.

MRS. SINKINS, large white Pink; Chrysanthemum Mrs. Douglas (white), Elaine, Ethel, Henri de Molesine, extra good plants, 1s. 3d. per dozen, cash with order to—CRUDGE, Park Gate Nursery, Taverne Close, Blandford.

COLEUS.—Brilliant colors, 12 large plants, 1s. 9d.; 1 Indian-rubber plant, 1s. 3d.; 12 Carnations, 1s. 12 Maiden-hair Fern, 1s. 3d.; 50 Labels, 1s. 3d.; beautiful Crotons, 1s. 3d.; 50 Heliotropes, 1s. 3d.; Cuttings, 6d. dozen; Geraniums, Pachelias, Marguerites, 1s. 11d. 100; Passion-flowers, Honnyuckles. Seeds, 2d. packet; 12 for 1s. 6d.; Primula, Cineraria, Calceolaria, Begonia Ferns, Palms, Aquilegia, Cyclamen, Gloxinia, Grevillea, Cucumber, ridge and frame, Lobelia, Dahlia, &c., free.—TURNER Thatch-hatch, St. Helens.

70,000 SPRING BEDDING.—12 Double Geraniums, 1s. 3d.; 12 Polyanthus, 1s. 3d.; 12 Auricula, 1s. 3d.; 25 Tuted Pansies, 1s. 3d.; 50 Dahlias, 1s. 3d.; Chrysanthemums; Cuttings, 100 mixed, 1s. 3d.; 50 whites, 1s. 3d.; 25 in 12 best named sorts, 1s. 3d. Special offer of Maiden-hair Fern, 12 strong plants, 1s. 3d.; 50 froids, 1s. 3d.; 25 Amateurs' Garden Guide, 64 pages, 100 illustrations, 7d., post free.—TURNER Thatch-hatch, St. Helens.

LARGE-FLOWERING BEGONIAS.—Good strong tubers, don'ts and storgie mixed, various colors, splendid tubers, 2s. 3d. and 3s. 3d. doz., free. Write for List. BADCOCK, Broad-street, Ottery St. Mary, Devon.

CLEMATIS, &c.—10 var., 3s. (all colors); 6 var., 1s. 3d. Roses, 30 var., 2s. 12 Climbing var., 3s. strong, free. Cucumber seed (Lat. Rol. 33) 1s. 3d. 100, &c. See bargains Bazaar.—BROUNT, Rothfield, Surrey.

NOW READY, price 12s., post free, 13s.—The Garden, Vol. 62, to be published, 1893.—Of all booksellers, or from the Publishers, George and Charles, Strand, London W.C.

J. DERRICK'S

Cheap Plants, Carriage Paid.

ALL STRONG PLANTS

12 Roses on own roots, 11 to 3 ft. high, Gloire, Homberg, Revo d'Or, Abel Carriere, Sir J. Paxton, Feciere, Margot, Souv. d'Elise, &c., 12 var., 1st. free	4 8
5 Dentals gracilis, strong, 11 ft. high	2 3
8 Mrs. Sinkins Plaks, strong clumps (12 for 1s. 3d.)	1 3
12 Iceland Poppies, white or yellow	1 6
6 Perennial Pyrethrums or Delphiniums	1 6
12 Perennial Calliades	1 6
6 Lychnis chalcedonica, scarlet perennia	1 6
20 Seedling Carnations, from double sowers	1 8
12 Hollyhocks from choice double flowers	2 3
6 Variegated Ivies Gold and Silver (12 for 3s. 6d.)	2 3
8 Ampelopsis Veitchi, small-leaved, strong, 2 to 5 ft.	2 6
3 Hydrangeas Dr. Hogg, best variety (12 for 3s. 6d.)	1 6
20 Foxgloves, white or spotted (40 for 3s. 6d.)	1 6
6 Violets Comte Brazza, double white (12 for 2s.)	1 3
25 Wallflowers, Harbinger, Bevoir Castle, &c. (50 for 2s.)	1 3
20 Perennial Lupines or Aquilegia	1 8
20 Canterbury Bells, double single	1 6
6 Arum Lilies (12 for 3s. 6d.)	1 6
3 Greenhouse Asparagus	1 8
8 Double Tropaeolum Hermonis Grasshoff (12 for 2s.)	1 3
5 Passion-flowers (5 var.) 1 Tacosa	1 6
3 Fuchsias, 6 var. each, best free	1 8
12 Tuberosa Begonia, good strain, assorted	3 6
6 Perennial Michaelmas Daisy (Caryanthemum maximum)	1 6
12 Alpine Auriculas, "Bettis" plants (500 per pkt.)	1 8
6 Aspidistra, 6 var., best free	1 6
12 Double Carnations, mixed, strong layers	2 6
6 Hardy climber (Jasmines, Honeysuckles, Virginian Creepers, Clematis, &c.)	1 9
6 Primula cashmeriana or cortusoides (Seed 3d. pkt.)	1 8
6 Achillea, Pyramis, double white	1 6
12 Chrysanthemum, best kinds, named	1 9
6 Ivy-leaved Geraniums, 6 var.	1 6
3 Palms and 3 Cyperus	1 0
6 Lovely Maiden-hair Ferns, 6 var.	2 0

Any 11s. worth may be selected from the above list. All plants carefully packed and carriage paid. Satisfaction guaranteed for cash with order.

J. DERRICK,
PORTISHEAD, near BRISTOL.

CARNATIONS.

My new Catalogue for 1893 is now ready, gratis and post free to amateurs on application. It comprises nearly 700 of the newest and best English, French, and German varieties in cultivation, with hints on Carnation culture.

WEGUMLIN, Blandford, Teignmouth, Devon.

RARE OLD DOUBLE GRIMSON POLYANTHUS.

BEACONSFIELD type of Single Polyanthus, yellow, white, fancy, and laced, 1s. 3d. doz. Fancies, best Scotch, named, 3s.; unnamed, 2s. dozen. Funks, named, 5s.; unnamed, 2s. Careatious J. C. is the raiser of some of the popular sorts named, 5s.; unnamed, 3s. 6d. doz. Gloire de Nancy, the largest, clove-scented white, Old Grimson Clove and Red Iris, the best for outdoor, 2s. 6d. doz. Auriculas, choice, 1s. 6d. doz. Begonia, lains and Cannell's, best named, large tubers, 1s. 6d. singles, 2s. doubles, Arum, Little Gem, 1s. 3d. each, the above all in strong plants. *Mullus moschatus*, *Hore-pollo* (double Musk), 3 strong plants, 6s., post free.

Post free, cash with order.
CROMBIE, Barrow-in-Furness.

ASKEW'S CRESTED NATIVE FERNS. Blandford, Dorset, 1893. Free Culture, 60s. 1s. 100. **W. F. ASKEW, Borrowdale Hotel, Keswick.** Illustrated Pencil Culture.

FUCHSIAS.—The newest and best, nicely rooted for growing on 12 all dissimilar, named, 2s., free.—BATEMAN, Warrington, Hastings.

GERANIUM E. V. Kaspall, finest for every purpose, autumn rooted, 2s. doz.; 12s. 100, free.—JAMES BATEMAN, Warrington, Hastings.

DELARGONIUMS.—Double Ivy-leaf, strong plants, finest varieties, 1s. distinct, named, 3s.; 6 for 1s. 9d.—JAMES BATEMAN, Warrington, Hastings.

FERNS (Evergreen).—12 hardy large-rooted ferns, 7 kinds, 2s. 6d. doz. 12 new and rare Hart's Longfin, registered, 7s. 6d. 20s. of *Gentiana verna*, 2s. 6d. Catalogue, 1d.—F. O'KELLY, Clonmulla House, Ballyvaughan, Co. Clare.

GIVEN AWAY.—Having sown all seeds I require, will send 20 packets, all named and different, free, 1s. including New Oriental Hop, Comet Aster, Mignon Aster, Triumph Aster, 9 o'clock, Shirley Poppy, Nicotiana, and given gratis to every purchaser 3 seeds of that novelty, new self-sowing Japanese Cucumber, all new seeds.—G. F. LETTIS, West Haddon Rugby.

GIVEN AWAY on account of REMOVING.—I have more seeds than I shall require, so will send 20 packets free for 1s., including Mignon Aster, Comet Aster, Scarlet Triumph Aster, Japanese Hop, Swan Poppy, Nicotiana adina, Stock, and all New Seeds. Given gratis to every purchaser 12 seeds of that new Aster, Cambridge Blue.—G. LETTIS, The Chase, Kilmington, Northampton.

REMOVING.—Expiration of Lease.—50 Corn-sowers, blue pink, white, 1s.; 30 Pansies, from choicest named German seed, 1s.; 20 Sweet Williams, 1s.; 50 Wall-flowers, Blood Red, 1s. All orders over 1s. carefully packed and carriage paid.—G. LETTIS, The Chase, Kilmington, Northampton.

COLEUS! COLEUS! COLEUS!—From one of the best Collections in England, including the most handsome varieties that have been sent out, as Beckwith's Gem, Brighton Gem, June, L'Etrole du Sud, Veusius, 51. Coleus, Blood Red, 1s. 6d. order over 1s. carefully packed and carriage paid.—G. LETTIS, The Chase, Kilmington, Northampton.

W. THOMPSON, Seedsman, Taverner-street, Ipswich, begs to announce that the 38th Edition of his **FLOWER SEED CATALOGUE** is now published. It includes many interesting novelties, in addition to all established favourites. Should be seen by all lovers of hardy plants. No English Seed Catalogue contains so large a number of herbaceous and alpine plants. As evidence of the reputation his seeds have obtained, W. T. begs to state that he has received unqualified and extensive orders for the Chicago Exhibition. Post free on prepaid application.

HENRY & CO.—GERANIUMS, very fine, all autumn-struck: *Veusius*, West Brighton Gem, Raspell Virgo, Marie, Mme. Thibaut, all 1s. 3d. doz. H. Jacoby, 1s. 3d.; Silver, 1s. 3d.; Broeze Czar, 1s. 4d. Dble. Salmon, 1s. 3d.; 1 doz. each of above for 3s. 3d. 6 var. 8 best named Dble. 1st. Geraniums, including Coridon's Glory, 1s. 3d., all free.—HENRY & CO., near Amerham, Bucks.

AMPHILOPS VEITCH, 5 for 1s. 3d.; *Dianthus* Napoleon 111., 4, 1s. 3d.; *Thlas*, 2s. doz., including Souvenir Sales and Mrs. Welch's Viola Duchess of Fife, 4, 1s. 4d., all free.—HENRY & CO., near Amerham, Bucks.

DEVON & CORNWALL ROCKERY FERNS, including *Osmondia*, 50, 2s.; 100, 5s.; extra large, 100, 7s. *Osmondia* regalis, 6, 2s.; 50, 10s. *Primo* rose plants, 50, 1s. 6d.; 100, 3s. 3d.; extra large, 50, 2s. 6d.; 100, 4s., all free.—BROWN, Brooklander, Kingtonwell, Devon.

PERNS, all hardy.—*Oreopteris*, *Osmondia* viridis, *Polytichum*, *Scolopendrium*, *Paraly*, *marium*, *viridis*, *Cat*, *Beoch*, *calcarum*, 4s.; 15 distinct, 1s. 6d.; 20 extra large rockery roots, 2s. 6d.; 50, 5s.; 100, 9s., correctly named.—J. HARRISON, Blandford, Keadal.

MY PENNY PLANTS ARE READY.—12 each for 1s. 3d.; 24, 3s., free.—Fuchsias, Geraniums, Heliotropes, Musk, Mimulus, Coleus, Scented Verbena, Double Primula, Veronicas, Chrysanthemums, 4s. 1s. 100 distinct Fuchsias, Mrs. Hill, Molesworth, and other choice varieties, 1s. 6d. 12 Geraniums, 1s. 6d. Tomato-plants, *Conferencia*, *Perfection*, *Peach*, and other kinds, good early plants, 12 for 1s. 6d.—GARDENER, Old Vleage, Sparrowton, Norwich.

STRONG PLANTS.—Soon bloom. 12 each *Primrose* hybrids, *Polyanthus*, *Choice Pansies*, *Sweet Williams*, *Wallflowers*, *Forget-me-nots*, *Seedling Carnations*, *Isola*, *Perennial*, *Oriental Poppy*, *Alpine Anemone*, 8 *Pinks*, lot, free. 1s. Vegetable plants, 250 *Onion*, 40 *Lettuce*, 20 *Cabbage*, 10 *Red*, free, 1s. 6d. *Daisies*, 50 fine red, 25 *White* Queen, 25 *Hen* and *Chicken*, free, 1s. 6d.—J. DUCKER, Haxey, Bawtry.

SWEET PEAS.—New and beautiful varieties, most brilliant and diversified colors, 50 for 2s. 6d.; 100, 4s. Strong plants, post free.—HOLE, Teignmouth, Devon.

CHEAP SALE of my Splendid Collection.—100 hardy flowering plants: *Carnations*, *Pinks*, *Pansies*, autumn Astors, *Double Bookets*, &c., free, 2s. 6d.; half, 1s. 6d. J. HARRISON, Keadal, Co. North, Ireland.

AURICULAS.—Green-edged, Grey-edged, White-edged, and 8s.; 1st. *stipine* Auriculas, all named, true to name.—W. WHEAT WRIGHT, n.e. Mr. Humphreys, High-st., Old Windsor, near Sloughbridge.

HERBACEOUS (spotted) Calceolarias.—Strong, stout, healthy plants. *Kelley*, 1st. First Flye strain, 2s. 6d. doz.; 100, 10s. carriage paid.—H. BLANFORD The Dorset Nurseries, Blandford.

DROVER'S BOOK on the Chrysanthemum should be read by every amateur grower desiring success. Hundreds testimonials all parts of England, New Zealand, and Australia, post free, 1s. 3d.—NURSERY, Fareham.

CARNATIONS, HOLLYHOCKS, LILIES.—*Lilium stratum*, 4 to 9 inches round, 3, 1s. 6d.; 9 to 10 inches, 2, 1s. 6d.; album *Knutzel*, 2, 1s. 6d.; rubrum *orientum*, 2, 1s. 6d.; double *Tiger*, 3, 1s. All sound Japanese bulbs, all post free. *Carnations*, *Baltimore*, 100 *Crimson* *Gloire de Nancy*, 3s. 6d.; 50, 10s., post free. Double *Hollyhocks*, various colors, mixed, large year-old plants, 2s. 6d. dozen, post free. Seed, Plant, and Irish Catalogue gratis.—W. & A. SHEPARD, Ivy-road, Hounslow.

CHRYSANTHEMUMS.—PANSIES.—Named Chrysanthemum cuttings, rooted early kinds, 6 paise for 1s. 3d. Named bedding *Pansies*, various colors, large clumps (not single plants), 2s. 6d. dozen; 5, 1s. 6d., post free. Ordinary plants, 1s. dozen.—SHEPARD, as above.

SPECIAL OFFER.—ALPINES in bud: *Primula nivalis*, *Primula rosea* var. *grandiflora*, and *Gentiana scabra* (clumps), 1s. each, free; 7s. 6d. per dozen. *Kelley*, the great *Pyrenean Saxifrage*, and the *Alpine Rose* (*Rhododendron hirsutum*), young, but vigorous and healthy. *Chrysanthemum* free for cash with order. General Catalogue of Alpines and Herbaceous, 4 stamps, post purchase.—Address MANAGER, Guildford Hardy Plant Nursery Guildford.

INVALUABLE BOOKS FOR AMATEURS.—"Greenhouse Guide," 7d., free. "Gardening Guide," 6d., free. "Pencil Culture," 6d., free. "Begonia Culture," 6d., free. "Poultry Guide," 6d., free.—MORLEY & CO., Preston.

CARNATIONS AND PICOOTEES.—Finest named varieties for exhibition. My selection, 5s. per dozen. Extra Rio plants of "Germania," best yellow self, 8s. 12 for 5s., post free. Cash with order.—T. LORD, Haleslitham, Tottonside.

ICELAND POPIES.—Yellow, white, and orange, mixed, 1s. per doz., free.—JOHN TURNER, Wetherby, Yorks.

STOCKS AND ASTERS for Exhibition. A speciality. Large-flowering *Tenace* *Stem*, mixed; *Victory* Aster, mixed; *Trafford's Peony* *Garden* Aster, mixed. All the above contain a great variety of colors, no better can be had. Each, 6d. and 1s. per pkt.—JOHN TURNER, Wetherby, Yorks.

BEGONIAS.—3 very choice large-flowering for pot culture, assorted, 2s. free. Cash with order.—JOHN TURNER, Wetherby, Yorks.

CINERARIA.—French strain, far superior to English in size and colour of flowers and habit of plants, 1s. per pkt., free.—JOHN TURNER, Wetherby, Yorks.

GERANIUMS (Bedding).—Early autumn-struck, well-rooted, and healthy: *Henry Jacoby*, 1s. 3d. doz.; 10s. 6d. 100. *Master Christie*, *Flower of Scarlet*, *Bon*, 1s. 6d. doz.; 9s. 100. *Tom Thumb*, *Jean Sibley*, *Scarlet Veusius*, 1s. 3d. doz.; 7s. 100. *Cristal Palace* *Gem* and *Bronze*, 2s. doz., free.—JAS. MORFETT, Robertshridge, Blandford.

LOOK AT THE finest Carnation grows, The (Government) *Paris* *France* *England*, *free*, *other* *sorts*, *free* on application. **HARRISON**, Keadal, Blandford.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS ON WALLS.

ONE of the methods a person can adopt who has no glass accommodation, and who yet wishes to have a show of Chrysanthemums, is that of growing the plants at the foot of a wall. One with a south aspect is decidedly the best; in the absence of this a fair aspect of success may be expected from east and west walls. If some means could be devised whereby a temporary covering could be given to the plants in case of frost, success is then assured. A broad coping-board fitted to the wall at the time the plants are expanding will be extremely useful in preventing the blooms becoming soaked with wet by continual rains or heavy fogs in the month of November. It is by frost following quickly after rain that the bulk of the flowers are spoiled. The chief point to observe is to plant varieties that are more suited to flowering out-of-doors. For instance, the reflexed sorts are much the best, the water not lodging readily amongst the florets owing to their imbricated form. The reflexed Japanese varieties and the Pompons are good, the latter especially flowering freely, and last in a good condition a long time. Now is a suitable time for putting out the plants. The old roots or stools that flowered in pots last year are preferable to plants raised from cuttings this season, owing to the extra number of shoots produced at the base, and are better furnished with branches to begin with. Remove part of the old soil from the roots, and plant close to the wall at a distance of 4 feet apart. If the soil is fairly good add some manure, but if rich give none, as a gross growth is more likely to be injured by frost, and is not so productive of flower-buds as that which is moderately vigorous, yet matured. Tread the soil firmly about the roots; a loose rootlet medium is not conducive to a desirable growth. At the distance named, plant the large flowered varieties; between each of these plant one Pompon or single flowered variety, which will cover the bottom part of the wall. If the plants were of good size the previous year they will start into growth with many shoots. Select six of the strongest on each plant, removing all the others, except the Pompon, which may have eight growths. When the branches are long enough spread them out thinly and fasten to the wall either with nails and shreds or with a wire run along in front of the shoots and fastened occasionally to the wall, constantly securing them as growth proceeds. Do not top the branches. When the first break takes place select two of the strongest shoots on each original stem, or more if space will allow, some kinds requiring less space than others owing to the length of their foliage. The shoots may be trained as close together as possible, consistent with allowing the foliage just sufficient space without overlapping. If the wall is less than 6 feet high, and tall-growing sorts like the Maid of Guernsey or Maiden's Blush, for instance, are planted, the shoots must be

trained in a slooting direction, or the flowers will be above the top of the wall. If the Pompons have to cross the stems of the large-flowered section near the base, a portion of the leaves of the latter should be removed to prevent overcrowding and give light to the small-flowered section. As soon as the roots have taken possession of the new soil apply liquid-manure in a weak state, and clear water liberally during dry weather. After a hot day thoroughly syringe the plants, this greatly assisting in keeping the foliage clean and in a healthy condition. Constant attention in training the shoots produces a much better effect than allowing them to hang from the wall, rendering the branches crooked and unsightly.

E. M.

3378.—**Chrysanthemum "Oyolone."**—This family belongs to the Japanese section; in colour cream.—E. M.

— This is a Japanese variety, and described as so enormous flower. The central petals creamy-white, arranged in whorls, and composing a boldly shaped bloom. It has been shown as much as 11 inches across.—C. F.

3409.—**Names of Chrysanthemums.**—"Medicus" will find the following varieties suitable, although I hardly know what is meant by the "natural system." What I suspect is required are varieties that will produce a goodly number of fairly large blooms without restricting their number to the orthodox three flowers to a plant, but still managing them somewhat after that style. Plants grown under the big-bloom method will very easily give, say ten fairly sized blooms to a plant, by selecting the terminal buds and allowing five shoots to remain instead of three when the plants make their first natural break in April or May, as the case may be. When the next break occurs in August by the formation of another flower-bud each shoot must be allowed to retain two growths instead of removing all and retaining the flower-bud, as in the case of extra large blooms being required, and but three to each plant. The first twelve are selected from the largest and best sorts: Avalanche (white), Stanstead White (white), Sunflower (golden-yellow), Edwin Molyneux (crimson and gold), Mrs. Falconer Jameson (cheat-out-bronze, tinted and striped yellow), Miss Marie Hoate (creamy-white), Puritan (bluish-white), W. W. Colea (bright-red), W. H. Lincoln (pale-yellow), Mrs. E. D. Adams (white, faintly blushed), Florence Davis (greenish-white), Col. W. B. Smith (old gold, tinged with terra-cotta), Japanese reflexed: Maiden's Blush (bluish-white), M. William Hoimes (cheat-out-red, inclined to dark crimson), Val d'Andorre (orange-red), Edwin Beckett (golden-yellow), Mrs. E. Beckett (bluish-white), W. K. Woodcock (deep-crimson), Bouquet de la Dame (white), Eyesford White (white), Mrs. J. S. Fogg (chrome-yellow), Miss Lacroix (white), Sarah Owen (golden-bronze), Gaiete de Rocher (bright orange-amber, flushed crimson). In-curved: Empress of India (white), Golden Empress (golden-yellow), Lord Alcester (pale yellow), Golden Queen of England (pale yellow, veined bronze), Miss Gifford (pale yellow), Lady Dorothy (pale cinnamon buff), Princess Teck (bluish-white),

--	--

Mrs. Heale (creamy-white), Mrs. Norman Davis (rich golden-yellow), Queen of England (rosy-blush), Jeane d'Aro (bluish-white), Mrs. Robinson King (golden-yellow).—E. M.

3183.—**Sulphuric acid and weeds.**—Sulphuric acid is a powerful poison, and requires much with great care for the destruction of weeds. If the acid is diluted with thirty parts of water and applied to weeds on gravel-walks when the surface is fairly dry it will kill them. You will, however, find that sulphuric acid is more costly for this purpose than the ordinary liquid weed-killers that are often advertised in GARDENING.—J. C. C.

— Half a pint of the acid to a gallon of water will destroy all weeds. The acid and water is applied through a rose pot, enough being given to moisten the surface of the gravel. It is very destructive to water-pots and metal pots of all kinds. Shoes and clothing also suffer if the acid is not carefully used.—E. H.

3313.—**Culture of Nertera depressa.**—This charming little berry-bearing plant is of easy culture. It requires plenty of moisture at the roots, and a considerable amount of atmospheric humidity during the growing season, with protection from hot sun. A compost of loam and peat in equal parts suits it very well, and the pots must be well drained. From the seed of June till October the best place for it is the north side of a wall or hedge. This cool treatment gives colour to both foliage and berries.—J. C., *Byfleet*.

3330.—**Anemones from seed.**—Sow in oces in pans or boxes in light sandy soil. Place in a cool frame or cool greenhouse till the young plants appear. Be careful never to allow the soil to get quite dry. When the seedlings are large enough to handle, plant them out carefully, 4 inches apart, in ground that has been well stirred and enriched with rotten dung. Keep them watered in dry weather, and many of them will bloom in autumn, and all will be strong enough to make a show the following spring.—J. C. B.

3384.—**Tarring wood.**—I do not think you require anything to mix with the tar to induce it to dry. In fine dry weather it will dry sufficiently in a few days to handle; a little benzoline used with the tar will make it work better when using it. The benzoline will not mix with the tar—it will float on the top—and sufficient care be taken up with the brush each time to make the tar work as easily as thin paint, and does away entirely with the tiresome and expensive plan of heating the tar.—J. C. C.

— Tar dries so well and does not come off upon the hands when mixed with pitch, except in hot sunshine; but the best way to treat a wood border is to sprinkle the tar thickly with coarse white sand as soon as it is applied. Throw the sand against it violently in small handfuls until the wood is thickly coated with it. The sand hardens upon it, forming a hard permanent surface, which lasts well and prevents the tar coming off.—J. D. E.

— When the tar is applied hot in dry weather it soon dries. The best way to treat a temporary display with bricks and ball the tar in an old iron pot. If the tar is to be used on a plot or a little more of turpentine oil. This will facilitate drying.—E. H.

GARDEN WORK.

Conservatory.

This shade will be beneficial now for plants in bloom. The sun is sometimes very hot in cloudy days in March and April, and to keep flowers in perfection as long as possible shade is necessary during the hottest part of the day. Spireas in bloom and coming on will require water several times a day, or, better still, stand them in saucers or pans. Shift on Chrysothamnus and place in cold pit or house. All they require is protection from frost, and this can generally be obtained by coverings at night. Give all the air possible when mild and calm. The best potting material is old turf with the fibre still in it, but the Green roots dead. This is broken up with the beds into small pieces and mixed with a third of old manure with a little sand and a small portion of calcined oyster-shells; broken ones will do well for this shift. Later on the compost may be a little richer, either by the addition of some artificial manure or a little bone meal. A light sprinkling of soot is also useful. Pot firmly and leave plenty of room for water. As regards stopping the shoots, where specimen blooms are required, stopping is not recommended, but for conservatory decoration these long unstoppped plants are not so satisfactory. A fine bloom that requires to be examined from the top of a tall stem is not generally satisfactory. Plants for furnishing out flowers or for the conservatory may be stopped in due time, but stopping and pinching the shoots should ever be done at the same time, the why and whereof of which scarcely needs any explanation, as the principle runs through everything and may be freely stated—never give more than one check at a time. Cuttings of Chrysothamnus rooted now will do useful work, though the flowers will not be large. Plants in less-to-houses should of course be rooted so that they may not become needed or naked at the bottom. See that all inside borders are moist. Give liquid manure to Roses planted out and in pots. Plants of Campanula pyramidata, white and blue, should be shifted into their blooming pots. These will vary in size according to size of plants. Large plants may have 8-inch pots, next size 7 inches, and the small ones 6-inch pots. These are shown at the end of summer and in autumn; they are easily raised from seeds, and if well attended to they will flower the second year. A group of Gladioli coming into bloom is always attractive. These are worth more attention. Large plants in good condition need not be reotted annually, as vigour can be kept up by the moderate use of stimulants. Ivy Pelargoniums grown into specimens are always effective. Some degree of training is necessary, either by using stakes or wires. Three or four wires bent over and both ends thrust in the pot, so as to form a cone-shaped trainer from 2 feet to 3 feet high, is a simple, easy mode of training. Named Cinerarias which have done blooming should be moved to a cooler pit to develop the suckers at the base. Primula seed which is now ripening should be looked after.

Stove.

The stove as a rule does not require much ventilation at this season, though no hard and fast rule should be laid down, as these structures vary so much in size and character, and each house in the matter of ventilation, shading, &c., should be especially studied. Too much shade is always injurious, and too much cold, dry air rushing in drinking up all the moisture is even more so. At this season, when the days are bright and the air cool, it is better to temper the sun's rays with a thin shade than to keep down the temperature by much ventilation. It is difficult to avoid overcrowding in this house now, for plants are growing freely. If there are mealy-bugs on any of the plants it will be a mistake to seek relief from overcrowding by moving any of the plants to the Veranda. This is sometimes done, but it is very risky. It will be found far better to throw out a plant or two than run the risk of filling Verandas with mealy-bug. Ailanthus and other flowering climbers must be grown in the light to obtain a good crop of flowers on the young wood. The usual way to train the shoots near the glass on trellis or strings, and when the frames of blossom can be distinguished to take them carefully down and fix them on the wire trainers. Basket-plants will require a good deal of water now. When a thorough soaking becomes necessary, take them down and dip in a tub or tub. There should be a tank for supplying water with the chill off in every stove.

Unheated Greenhouse.

When Tuberos Begonias are wintered in pots, or celloars, or other frost-proof buildings, they may be brought back now to the greenhouse. I should not report yet. Let the growth start away first, and when the shoots are an inch or two long shift into larger pots, removing a little of the old soil without disturbing the roots overmuch. Very pretty are these Auriculas now. The outline of choice Primulas and Polyanthus may be combined with Auriculas, as all thrive under the same conditions. It will, of course, be borne in mind that this family requires good hum, and they cannot bear much hot sunshine. Tree Ferns are bright and showy, and may be grown well to pots. A collection would be most interesting and should be plunged outside in summer, after the wood had been hardened a bit, and the house then given up to Lilies, Fuchsias, and Tuberos Begonias, with a few odds and ends thrown in.

Mushroom-house.

New beds may still be made up to the house, but the season is at hand. Mushroom-beds will do as well in the open air, as unless the house stands in a very cool position, Mushrooms in summer will get maggoty and be useless. The best stimulant to revive flagging Mushroom-beds is dilute of soda, half an ounce to the gallon, and it should be applied warm. All roots of Ribwort, Sea-kale, and other things, the produce of which have been used, should be taken out. Old Mushroom-beds as they become exhausted should be cleared out also, as they lead to the increase of woodlice and other insects.

Sowing Greenhouse Annale in Hot-bed.

Many things may be raised from seeds sown in hot-beds now that will be useful for the greenhouse later. Cocks-combs, both the old-fashioned kind and the lathery plumose varieties, and Celosias can be grown to a very

useful size to a short time from seeds. Mignonette, Balsam, Thunbergia alata, Cobaea scandens, and Mirandraya Barclayanii, Gloriosa, and the various Begonias may be sown now also Primulas and Cinerarias in Blue Gums and Cannes, especially the new large-flowering varieties. If the seeds of the Cannes are soaked in warm water 24 hours they will germinate immediately.

Cold Frames.

Tender plants will require warm covers at night. Two thicknesses of mats will be required if mats are used, but straw covers are cheap and very efficient in keeping out frost. Water only in the mornings of fine days at pressure, and it is better to keep the plants on the side of dryness at the roots for awhile, until there is a marked change in the weather. As soon as the seeds of Stocks, Asters, &c., have germinated move to cold frame, and ventilate to keep growing steady.

Window Gardening.

Pelargoniums will soon be coming on, and every effort should be made to get rid of green-fly before the plants open a flower. Roses are not much grown as window plants; the reason is, probably, they last but a short time, and the plants in the half-stay condition in which they are generally seen are not good to look at. Very many hardy plants grown for early blooming (Roses among the number), are much injured by being turned out before the growth has been ripened. Where Roses are grown to windows at all, the Polyantha roses will give satisfaction.

Outdoor Garden.

Evergreens may be safely transplanted now. A good deal depends upon the way in which the land has been prepared. Where the ground has been trenched and priviered by exposure, trees and shrubs will stand a much better chance of growing than if holes are dug in unworked land. When shrubs or trees are moved from a sheltered to an exposed position, it is always desirable to afford some shelter the first month or two, or until the period of cold winds are past. There are cheap and simple ways of doing this. Stout stakes driven to on the windward side, and evergreen or other branches used to form a shelter by winding them between the stakes. A few sometimes used a double hurdle to break the force of the wind, and these answer very well. Brush faggots with the thick ends fixed in the ground form a good shelter. Groups of Tricomas are very effective near masses of shrubs on the lawn, jut out from them as it were. They offer a striking contrast to groups of Pampas Grass and masses of Polygonum cuspidatum. All of these things may be planted now; better let the Grass grow close up to the plants without any formal or exact margin. Very pretty in the borders have been several large groups of Oxycodons, Lucille (Gony of the Snow). These may be sown in the spring. Hepaticas at this time should prepare the ground by working in a plenty of leaf-mould with sand, if the ground is heavy. A shady spot suits them best, as it does also Cyclamens and Dog-tooth Violets. Divide and replant Violets cornuta and V. lutea. Plant out toiled and other Panicles still in cutting beds. Plant out edgings of hardy plants, these will include Bedum Saxifrage, House-leek, Lavender Cotton, &c. Book work may be altered and extended now. Sow hardy annuals in quantity.

Fruit Garden.

Pines should now receive the spring shifting. Those specimens which require larger pots should receive present attention, and the bottom-heat should be overhauled and, where necessary, renewed. Most Pine-growers have soil choppers up to the plants, and these should be covered days before a start is made. Pots also of the most perfect kind prepared, so that when the weather is suitable the work can be rapidly executed. Where Pines are grown largely the shifting at this season and the renewal of the bottom-heat or plugging beds must be done very promptly. Good turfy loam, more or less enriched according to quality, will form the basis of all Pine growing. A little old manure or bone-meal with a sprinkling of soot is always useful. Press the soil firmly in the pots and where possible remove a leaf or two from the bottom of the plant so as to drop them a little deeper in the pots, and encourage the production of new roots. Give the final thinning to Peaches in early house which have finished stooled. As a rule, I do not recommend many surplus fruit to be left on so long as this, still, a final look round should be given and where too many fruits have been left reduce the numbers. Small Peaches have but little value in a commercial or, indeed, any other sense, and this means rather severe thinning. One to a square foot may be taken as the correct distance apart. Peaches will be a good deal of nourishment in the way of stimulants, but if they are watered too long or the flavour may suffer. When the first lotting of colour appears discontinue the use of stimulants. Grapes hanging to the room must be looked over frequently. A good stock of Lady Down's in good condition would be worth money now, though Grapes are very cheap owing in comparison with what they were thirty years ago. Keep up the succession of Strawberries by introducing the requisite number of plants at fortnightly intervals. Continue to do grafting and look carefully after the blossom of fruit-trees.

Vegetable Garden.

Successional crops of Peas, Beans, Horn Carrots, Spinach, Lettuces, and small salads should be sown as required. Good Peas for pre-sock sowing will be found in Duke of Albany, Walker's perpetual, No Plus Ultra, and Victor's Perfection. Doubtless there are many other sorts of good quality, but not better than those mentioned above, and the cost of the seeds will be 50 per cent. more. The Green Woodcock is a good Bean for present planting. The Beans are a better colour when cooked than the broader varieties, and I do not think the very Broad Beans have much to recommend them for the table. The Herb garden may be rearranged now. Cuttings of Sage, Thyme, Mint, &c., will root now if planted firmly and supplied with water till rooted. If desired, seeds of Sage, Thyme, Lavender, Rosemary, &c., may be sown in many new beds of Mint, if the young shoots are out with a knife, a couple of leaves beneath the soil the out shoots will easily lift out with good roots, and it planted in beds 6 inches apart there will be Green Mint for gathering to a very short time. It is a good plan to have Mint in different aspects so as to have fresh Green Mint all summer. A patch in a warm sheltered spot will come in early, but the best supply will be under a north wall. Sow main crop of Beet about the middle of April generally. In very early districts the

sowing may be delayed till the end of this month or first week in May. Main crop of Carrots should be got in now, though the air is warmer here. Carrots may be sown in small quantities till middle of July for drawing young. Sea-kale coming on in open air must be covered entirely to keep the air and light from it. Earth up Cauliflowers and Cabbages. Drain soil to Peas and Beans and place sticks or other supports in good time before the tendrils start away. French Beans may, if desired, be started in boxes for planting on a warm border. Cauliflowers which have been raised in heat must be well hardened before planting out, and it is better to plant in rather deep drills. Tomatoes, both for sowing in cool-houses and also for covering walls or fences outside, should be kept moving, being shifted into larger pots as required. Cucumbers and Melons in frames will need careful management now, avoiding all checks either by injudicious watering or ventilation. E. HONDAY.

Work in the Town Garden.

At the time of writing the weather is exceedingly bright and warm in the daytime, but with frosty nights, necessitating the use of a good deal of fire-heat for tender plants under glass. Under such circumstances evaporation is very rapid, and a much better supply of water is necessary to keep them in a healthy and growing condition. At this season the forenoon is the best time to give water, or, at any rate, the chief part of the supply, though the stock, and particularly those in small pots, should be looked over a second time during the afternoon, especially in warm houses, where the pipes have to be kept hot during the night. After a thorough supply has been given to all plants showing the least signs of dryness, in the early part of the morning, the whole of the contents of the house should be liberally sprinkled with a fine spray of clean water, with the chill just taken off—set warm. Without an abundant supply of moisture plants in pots cannot make a healthy growth; and if the drainage is free there will now be but little danger of giving too much—that is, if no more is applied as long as the soil remains moist. Small seedling plants in boxes or pans must now be shaded from bright sun during the middle of the day, such as have been recently pricked off, in particular; shade is not necessary for all cuttings in process of striking. The best of established plants, such as Stocks, Snowdrops, Pansies, Fuchsias, Patulias, and other wall, however, be all the better for full exposure to all the sun there is at present; but take care to ventilate freely and in good time, so as to avoid a stuffy atmosphere. Cinerarias and Herbaceous Calceolarias should be lightly shaded on bright days, and if the foliage will, it is better to sprinkle them liberally overhead than to deluge the roots with water, though if the soil is found to be really dry this must be rectified also. No time should be lost in potting tubs of the Tuberos Begonia, and planting them in a healthy position to start, even with no more heat than that of an ordinary greenhouse; most of these are already on the move. If they can be plugged in a gentle bottom-heat for a time they will form roots more quickly and plentifully, but keep the tops near the glass with light shade from bright sun. Prick off seedlings into extra well-drained pans or boxes of lightly rich soil, leaf-mould and sand mixed, and keep them close and regularly moist. Tomatoes must be pricked off as soon as they can be handled. Keep them moderately warm, but not so hot as the Peas. Sow early in a frame or in boxes of Phlox Drummond in a frame or in boxes on a greenhouse shelf. B. C. E.

THE COMING WEEK'S WORK.

Extracts from a garden diary from April 1st to April 8th.

Prepared a piece of ground for planting with Violets to raise plants for growing in autumn. Maria Louise is the best I have tried grown. Some good flowering has been worked in. Shift plant Violets from middle of month. I find they make the strongest and best growth when planted in quite an open situation away from wall and buildings. The mats thing is to plant early, and keep them moving till it is time to plant in frames, which with us is about middle of September. Water will be given should it be necessary when the weather is hot and dry. Watered newly-planted trees and shrubs; they are, perhaps, not exactly suffering, but it is best not to wait till they are better before sending them to the open. They were much when planted, and so will be difficult to keep the soil near the roots moist. Sowed main crops of Beet and Carrots. Prepared trenches of late Peas. These are isolated with other crops between. Peas do so much better when the light falls on all sides. I prefer where possible to run the rows north and south, as the sun shines on both sides. Prepared trenches for earliest Celery; only just a row or two will be planted of this first crop. The plants are coming on to small pots, and in the meantime the manure is being shifted with the soil. Lettuces have been planted on the ridge. Sowed New Zealand Spinach in pots under glass. Two or three seeds are placed in the centre of each pot, and when the plants are hardened off they will be planted in patches a yard apart in a warm, sunny spot. Picked off Capsicums. Sowed in boxes Basil, Marjoram, and summer Savoy. Made oew bed of Mint. A good deal is forced, so new beds are made annually to get the roots strong, and to always have plenty in stock. Cucumbers under glass are growing rapidly now. Lights top-dressing a green frequently, as where the plants are doing well the white roots soon work through, and I would rather use little and often than put on a heavy top-dressing at one operation. Set early Melons. Thinned Grapes in second vintage, and dis-huddled and tied down young growths in late houses. I was much afraid our house of young Vines had been over-cropped last year. However, the Vines have broken well, and are showing plenty of bunches, so I suppose no great harm was done. They had one thing in their favour—they had received a heavy dressing of Silvers manure. Sifted soil among Pansies, Pinks, Carnations, and growing plants generally. Moved bedding plants into cold frames, and all cover with straw mats at night. Sowed Cucumber and Melon seeds for raising plants to fill pits and cold frames when the bedding plants are set out. Sowed a few more Vegetable Marrow and Ridge Cucumber seeds. Thinned Potatoes in early beds, but Alexander Manure and Waterloo have come out better than expected. It is not often these varieties are so good, but they will be required; but this season

* In cold or northern districts the operations referred to in "Garden Work" may be done somewhat later to a fortnight later than is here indicated with equally good results.

there has been a considerable number to pull off. Tied down young wood in Peach-house. To have San Peaches they must have generous treatment, and only carry a moderate crop. I should have been glad to have taken bedding and other plants out of this house earlier, but could not manage it. Planted out Hollyhocks, Gladiolus, and remainder of Carnations. Rolled and mowed lawns.

OUTDOOR PLANTS.

FINE GRASSES.

We regret that the noble Pampas Grass (here figured) is not more frequently seen than it is at present. When the plant came to the country first it was—perhaps because, being put in choice positions, and in good soils, it was more satisfactory—more common than it is now; doubtless, too, the very hard winters that we have experienced have sometimes caused its destruction. Its striking and handsome appearance make it worthy of a position in every garden, and as this is a good

were one or two forms of it in cultivation, and then there was the Yellow Nymph, a good thing in itself, but now so infinitely surpassed by Yellow Hybrid Water Lilies that it is not fit to occupy space in the same sheet of water. In any case it should not be where it comes into competition and contrast with the lovely things described below. Now we have Water Lilies with the flowers nearly 8 inches across, and the colours embraced are whites, flesh, pink, rose, carmine, and yellow, and all, let me impress upon my readers, as hardy as the common kind. For a long time tropical kinds had the monopoly of brilliant hues, and those who have seen the Lily house at Kew must have longed for some such colours for the outdoor ponds, where the flowers might be enjoyed without the fatigue of enduring hot temperatures. It is true the tropical kinds with blue flowers have no counterpart among hardy kinds, but then we have two yellow varieties, and this colour hitherto

and is well adapted for small pieces of water, but its value is diminished through the increase of fine hybrids. Then there is Caspary's Water Lily, which some call a distinct species, and others make it a variety of *N. alba*. At any rate, it is exceedingly beautiful, and I think I may say rare and very expensive, for the new kinds are offered at a much cheaper rate than this, although it grows wild in Sweden. It begins to flower earlier, and with the water at a lower temperature than any other kind. Its flowers in size and shape are like those of *N. alba*, but they are of a deep rosy carmine colour. It comes with a flush of flowers in May and June, but ceases in summer. There are many kinds to succeed it, however, and its earliness is a great point in its favour. The Sweet Water Lily is *N. odorata*, an American species introduced 100 years ago. It differs in many respects from our native kind, flowering profusely in deep or shallow water from June till autumn. Its flowers are white and sweetly scented. Some plants of this species have a decided red tinge in their flowers at the base of the petals, and one well-marked variety has been discovered in America, and called the Cape Cod Water Lily, having been found near Cape Cod, Boston, Mass. It is called *N. odorata rubra*; but the latter name is a little misleading, as one cannot truly call it red. It is, however, distinct from the Swedish kind, its colour being pure rose at the base, shading to pink at the edges and tips of the petals. It is a profuse bloomer, and the flowers open widely. Last year my group of six plants was not without flowers from the time they first appeared in June till late October, when the days became too dull and the water too cold for numerous bulbs then showing to develop.

N. TUBEROSA is a North American species, limited in its natural distribution, and uncommon in cultivation. It has not the long, thick, fleshy root-stock peculiar to most Nymphæas, but instead a thick, fleshy tuberosous mass of roots; hence its name. It is, however, easily increased, and should be more commonly cultivated. Its flowers are white, larger, longer and broader in the petal than those of other wild species, whilst one distinct trait it has is that its flowers are thrown up above the water several inches, those of most Lilies floating on the surface.

N. FLAVA is the only yellow kind ever found wild, and exists in Florida. It was for a long time a puzzle to the botanists, who supposed it to exist, but they did not know where. It was introduced into this country about twelve years ago, and although tolerably hardy, it has not proved very desirable in cultivation. Instead of having a thick rhizome, it has a mass of fibrous roots, and in addition it sends out long, runner-like shoots after the manner of a Strawberry, and these form young plants. The flowers are canary yellow. From its habit it could hardly be grown in a confined space, but there is no need to trouble about it. Doubtless it was one of the parents of M. Marliac's yellow hybrids, and we have its charming colour embodied in plants that stay at home, and for months keep sending up magnificent and immense flowers in unbroken succession. The last true species that has come under my notice is a pigmy kind, but a gem for tiny fountains, or for culture in a manner suggested below. It is called *N. pygmaea*, and hails from Siberia. Its leaves are about the size of the palm of a man's hand, and the flowers, which merely consist of four white petals, besides, of course, the inner parts, are, when open, only about 2 inches across. Now we come to the hybrids, that will do so much to make the whole family popular in the near future and greatly sought for. They seem to belong to two distinct types. One lot, to which M. Marliac has given his own name, has flowers larger in all their parts, and altogether considerably in advance of anything hitherto known or seen among Hardy Water Lilies. Another section in odour, and size, and shape of flower, without a doubt comes from the odorata type, and the name has been retained, adding another descriptive of colour. The giants of the family are the Marliacea kinds.

N. MARLIACEA ALBIDA surpasses all the white kinds in existence. It has great vigour of growth and leafage, and is yet a most elegant ornament in themselves—being purple-red when young, becoming a rich lustreous green with age.

Olysetrum argenteum. Pampas Grass (*Olysetrum argenteum*).

time for planting it, our illustration may have some effect in enforcing its claims upon our readers. It should be given good and deep soil.

HARDY WATER LILIES.

From time to time questions appear in GARDENING as to what to grow in water. In the issue of March 15th, query 3299 refers to the subject. Now water flowers are very numerous, but the Water Lily is the queen of all, and having regard to the fine kinds of recent acquisition, I have not the least doubt that when they are better known, all who have a pond of any size will want them. Few flowers are more satisfying. Tea Roses, Carnations, and other favourite flowers are charming, but they need constant care and attention; but our Water Lilies need no care at all, and they have a blooming season that begins in May and ends in November. I cannot say too much in their favour, nor praise them too highly. It is only the work of recent years that justifies making these flowers a prominent feature. The old White Water Lily always had plenty of admirers, for none could fail to be pleased with its simple beauty and spotless purity. There

only existed in a kind little grown, because of its peculiar habit, but now is embraced by two of the best sorts in existence. It is to the labours of M. Latour Marliac we are indebted for these acquisitions. Their actual parentage at present remains somewhat—in fact, entirely—obscure; but that is of little moment to those who have a sheet of water to adorn. It is far more important to know what has been done and how we can avail ourselves of things provided. Before describing the newer varieties I will say a few words concerning the older species, and this is essential in order to classify the hybrids, and refer them to the sources that their characteristics seem to indicate.

THE COMMON WHITE NYMPHÆA ALBA is known to all, being a native of ponds and rivers. It often is in flower before May is over, and in a wild state is usually finest where there is a depth of from 2 feet to 3 feet of water over the crown. Being so profuse and widely distributed it might be expected that natural variations would occur, and there are several varieties of it in cultivation, one being named *double*, its flowers being very double, with many more petals than those of the type. Another kind named *minor* has small flowers,

The flowers are simply immense, like great white deep saucers floating on the water, 7 inches in diameter, with a rich bright-yellow centre. The outer petals are very long and broad, but they gradually shorten towards the centre. Everyone who can grow a Water Lily should have this bold and handsome kind.

N. MARLIACEA CARNEA and **N. Marliacea rosea** may be described together, for they are counterparts of the preceding kind in vigour of growth and leafage, and holdness and immensity of bloom. The names rather indicate the colour, the first-named kind having flowers suffused with a pale flesh tint, and in the other the colour deepens into a rosy-pink. Last, but not least in this section, is the

CANARY WATER LILY (N. Marliacea chromatella). It is full of character and interest. The leaves, at first purplish-red, change to deep-green, with distinct and most beautiful marblings of a dark brown-red, whilst the flowers in size are like those of the kind above mentioned, but of a soft yellow hue, with a rich centre. It is now one of the commonest of the choice new varieties, and I note with satisfaction is becoming cheap, for all should have it.

N. ODORATA SULPHUREA is the other yellow variety and it is hard to say which is best. Certainly anything more lovely than this was with me through the latter part of last summer and autumn is inconceivable. It differs in many ways from the preceding kinds, but has prettily marbled leafage. The long pointed buds suggest a spear-head as they pierce the water, and they are quite 4 inches in length, opening into immense spreading flowers nearly 8 inches across. The last flower of this kind cut towards the middle of October last year was, when measured, of the dimensions here given, and its scent was most delicious. The colour in addition is deeper and more decided than that of the Canary kind, whilst the petals being long, narrow, and pointed, open widely and reflex, giving the flower a very starry appearance.

N. ODORATA ROSACEA is a perfect gem of exceeding loveliness, though considerably less in size of flower than the above named kinds. The flowers are about 4 inches across; it is very free blooming and the colour a clear bright soft-rose with yellow centre, and the sweetest of odours perfumes the flower. The petals are much narrower than those of the Marliacea series, and the flower is a perfect pink star, floating among rich-green leaves.

N. ODORATA EXQUISITA is the deepest-coloured kind that has yet been sent out, but otherwise it did not appear to me quite as lovely and attractive as the pure rose and yellow-hued sorts. There may be something in colour fancies, however, and, giving it its due, it is certainly the greatest advance in colour that has yet been made, the flowers being deep rosy-carmine—in fact, almost red—at the base of the petals. The young leaves are of a very rich-purple tint, becoming green when full grown. I believe the illustrious raiser of these lovely Lilies has further added to them, and doubtless fresh enterprises may be in store, but I speak only of those I know and have grown, and the pond will be beautiful indeed that is planted with them all. In my case, the pond was only an asphalt one, with a padding of clay inside of it. In order to isolate the Lilies from Typhas and other strong weeds present, concrete boxes were made for the plants, each one being 4 feet square and about 18 inches deep. This expense is rarely necessary, as a pond with a few inches deposit will support the plants, and they can hold their own against the smaller water weeds; it is the vigorous Rushes and Reeds that must be kept down and, if possible, exterminated. A simple and expeditious way of planting is to put the plants with soil in some shallow baskets and sink them to the bottom. Before the baskets have rotted the plant will have fixed itself to the bottom with fresh roots. The best season for planting is that now at hand—the spring. Plants put in in May even if only a few, will make sufficient progress to flower before summer is gone; the only exception in

my experience has been the Canary Lily, and this, in two instances, did not flower till the year after planting, but grew strongly nevertheless. A word might be said as to arrangement. It is best to have the pink ones nearest at hand, where they can be seen closely, and the yellow associate well with the pinks, whilst the whites may be in the distant parts, if such there are, as they are effective wherever placed. I imagine more will long for these Lilies than have means, or rather opportunities, for growing them. There is nothing like a lake, stream, or

Primrose "Munstead White."

pond, but, falling these, one may resort to other things with an amount of success. I have seen aquatic plants really well grown simply by sinking tubs in the ground and half filling them with soil and then filled up with water. Those who could afford it, too, might make brick and cement tanks in the same way as the boxes above mentioned, only to be sunk in the ground to a depth of from 2½ feet to 3 feet. These, with a foot of soil and the rest water, would grow excellent Lilies. It is a valuable quality these hybrids have in not wanting a great depth of water over their crowns. In the pond in question there was little more than a foot, and summer evaporation on several occasions reduced it to 8 inches or less, but still the plants kept flowering. It would be well, however, to arrange that at least a foot might cover them in winter, and then they are virtually safe from disaster. Possibly they might not be killed if frozen with the water, but I avoided the risk, because they were precious things, and expensive, too, when I first planted them, although they are reduced in price as the stock increases. Early in the season they manifest strange vagaries as to opening and closing; the opening being a short day of from 8 a.m. to 3 p.m. Later, however, they lengthen their day to nearly 12 hours, and open daily whether bright or dull, although at first they await clear sunshine before expanding, and on a dull day remain perfectly closed. I first found this out through a friend calling in the summer, and it was pouring with rain. I told him with regret he would not be able to see the Lilies, but, to my astonishment, upon going to the pond before 9 a.m., more than a score of splendid flowers stood wide open. A. H.

A USEFUL WHITE PRIMROSE.

The grower of a large batch of seedling Primroses of a good strain may always expect some pleasant surprises. Among seedlings of white and yellow hunch Primroses a few years ago appeared one of the plant of which a small group is shown in the above woodcut. Though from Polyanthus seed, it is a true single-stalked Primrose, of a clear white colour with yellow eye. It was once conspicuous from its very early and dense bloom, a character that its divisions always maintain, and it has proved one of the best for massing for spring effects. It is known as **Munstead Early White**.

3402.—Beds on a small lawn.—If not too much shaded, Tuberos Begonias would succeed well, as they are not adverse to partial shade, but will succeed also well in the full sun. There is now such a charming series of colours in a good selection that I think you will get

much pleasure from the flowers, and they will maintain a gay display until the autumn. It is too late now to raise seedlings for flowering this year, but you may purchase bulbs or young plants, which will not be very expensive, as the beds are not large. You might plant them with sub-tropicals if the space is not too small; but I think Tuberos Begonias would succeed best. An edging could be formed of the Variegated *Daotylin*, Golden Moneywort (*Lysimachia Nummularia aurea*), *Loebelia*, Golden Feverfew, or Tufted Pansies if the position is not a shaded one. Of course, if the beds are where the sun never shines, it is unreasonable to expect a gay display of flowers through the summer months. —C. T.

—The best thing you can do will be to plant the beds with *Violas* in belts somewhat as follows: centre—*Counicee* of *Hopetoun*, followed by *Bina Bell*, *Golden Queen*, *Admiration*, *Counicee* of *Kintore*, *Golden Prince Improved*, and *Bronze Queen*. This arrangement would have a very pretty effect and with a little attention would last throughout the summer. —A. G. BUTLER.

3379.—Viola and Lily of the Valley.—*Viola*s may be planted and readily increased during April and May. Use the healthiest and strongest runners from old stools, placing these about a foot apart in the row, and the rows one and a half feet from one another. *Lily* of the *Valley* should be planted early in March, just as it commences to grow, but before the crowns show any green. The old variety of *Viola* named *Czar* is a good and sweet-scented kind. So, too, is the improved variety; this is larger, but does not bloom so freely, nor smell quite so sweet. *Marie Louise* (deep lilac), and *Comte de Brazza* (pure white), are good double varieties, that are perfectly hardy. Choose a moist and partially shady place for the *Lily* of the *Valley*. —P. U.

—The present is as good a time as any to plant the latter, and the former may be transplanted as soon as good rooted runners can be had. These always make the best plants, and if put out a foot apart in good rich ground and a fairly open position, every one will make a good flowering clump by next winter. The best *Viola*s are the old Russian, *Victoria Regina*, *Welshiana*, and *argenteoflora* (single); *Marie Louise*, *De Parme*, and the *Neapolitan* (double purple), and *Comte de Brazza* and *Belle de Chateaux* (double white). All are quite hardy, and in a moderately warmed bed will produce flowers, more or less, during the whole of the autumn, winter, and spring. Always plant quite firmly. —B. C. R.

—The best time to plant *Viola*s is immediately after blooming is finished, usually in April. *Lily* of the *Valley* should be planted not much later than February. The hardiest and best *Viola*s for open-air blooming are the Russian, of which there are several varieties, including the *Czar* and the *Oiant*, both of which have larger flowers than the common variety. In warm situations the double blue *Marie Louise* flowers fairly well, but in severe weather the flowering ceases. I have often cleared the snow off the Russian *Viola*s and gathered flowers in the depth of winter. —E. H.

3385.—Treatment of *Spiraea japonica*.—After flowering the roots should be cut in two if more plants are required and planted in good soil in any open position out-of-doors, where they may remain to complete the whole of the next season's growth, after which they can be taken up and potted again. *Spiraea*s do not flower nearly so freely, neither do they make such good foliage, if grown in pots every year. They need a rest of at least a whole year. —S. F.

—If you turn the plants out of the pots just as they are (but having previously hardened them off) into a bed of rich sandy soil, and keep them well supplied with water, they will flower again next spring either in the ground or if lifted and potted in December. But they would do better still if divided into pieces with about three eyes each, and allowed a year's growth undisturbed. Or you may keep them in the pits, plunging these in ashes outside, giving plenty of liquid-manure through the summer, and repotting into a rather larger size about the end of the year. —B. C. R.

—It is much best and least trouble to turn these out in the border after flowering is over, but it will not do to expose them to too great a change in temperature. Keep the plants abundantly supplied with water while growing,

and stand them in a frost-proof pit or frame until the end of May; then plant them out in deep loamy soil, giving them one thorough soaking as soon as possible. After this they may be allowed to die down naturally, and will make good crowns for lifting the following season. If they receive a severe check, either from drought or cold, while in full growth, the crowns are of no use the next season. Few plants require more water than this *Spiraea*.—P. U.

This plant requires a great deal of water both before and after flowering, and, being a hardy herbaceous plant, it may be planted out in the open border, or, if it is intended to grow them in flower-pots for early forcing, they can be shifted on into larger pots, and will flower splendidly the following season, if they are not neglected during the growing season. Plants in 6-inch pots should be shifted into others 8 inches diameter. Use good rich potting-soil, such as is well adapted for Pelargoniums, Fuchsias, and plants of this character. The plants do best out-of-doors after the month of May. If they are planted out the thick mass of fibrous roots which have grown into a hard ball must be disentangled a little. Prepare a piece of fine, rather sandy soil, enriched with some decayed manure, water the plants well before turning them out of the pots, and plant firmly. Water them well until established.—J. D. E.

The plants should be well supplied with water until the growth ripens off naturally. The best plan is to harden the plants off and plant out in new soil and keep supplied with water. By the planting-out system less water will be required. Much with old manure or leaf-mould.—E. H.

3387.—**Violets for outdoor culture.**

In my opinion no variety beats the old and new Czar Violet, as far as single blues are concerned. Marie Louise is the best double blue, and Comte de Brazza (syn. Swanley White), the finest double White variety. April and May are the best times for making new Violet beds, and I find them much better if done annually. Choose showery weather if possible, and have your ground all ready, so that a good opportunity may not be lost. Healthy runners are the best. Place these 1 foot apart in the row, and 1½ feet row to row. Keep all runners off during the summer, so as to form a stouter crown, when they will mature and flower better. I leave a few to make runners at will, so as to form good sets for next season. Few subjects are increased more readily than Violets, every runner making a plant.—P. U.

By far the best plants are those obtained by planting out the rooted runners in April. This should be done annually, when splendid clumps for flowering the following winter or spring will result. If allowed to grow "at their own sweet will" they become overcrowded and starved in time, and then the flowers will be few, small, and poor. Rich, firm soil and plenty of water in hot weather are the chief secrets in obtaining plenty of fine Violets. (See also reply to 3379.)—B. O. R.

For purely outdoor growth the single kinds are the best, being more hardy than double varieties; but if a cold frame can be had the latter are much preferable for winter flowering. The rich mauve-levender-blue flowers of Marie Louise, the pale lavender-purple of De Parme, and the pure white Comte de Brazza are more appreciated than the single-flowered kinds, of which the Czar, or Russian, is the more hardy and free in flowering. All kinds are better for being divided and planted afresh annually. Violets will succeed in almost any situation, although much depends upon the character of the soil. What is known as sandy loam produces the best results and with the least trouble. Heavy, retentive soil is the worst; the plants do not make growth sufficient in that to enable them to flower freely. The soil ought to be moderately enriched with manure; too much induces too great a crop of leaves at the expense of blossom. Whatever manure is required should be added early in the autumn, when the soil is dry. In the case of that which is heavy it ought to be laid up roughly to receive action of frost, which tends to ameliorate it considerably. If a position facing south can be secured more blooms will be produced during the autumn and early spring. The middle of April is a good time to plant, either for extended plantations or for renewing the old. Plants that have flowered this season provide suitable plants for next year's supply. By pulling them in pieces every

bit with roots attached will grow, although, where a plentiful stock is available it is not wise to make the new plants too small. A space of 10 inches between each is sufficient. Showery weather for planting is best, the labour of watering and shading is avoided, it being necessary to do both during hot, dry weather. The same treatment in raising the plant is necessary in growing double-flowered varieties for the frames up to the second week in September, this being the best time for transferring the roots to the frames.—S. P.

FRUIT.

FRUIT AND FRUIT GROWING.

I WAS pleased to see "Salesman's" remarks on this subject (see page 740, Vol. XfV.), for although he says he cannot agree with some of my former remarks he fails to point out where I am wrong, and it is hardly to be expected that a grower like myself, who entirely dispenses with the salesman's aid in disposing of his goods, and have always both by precept and example urged my brother growers to do the same, as far as possible, should agree on all points with one of these, who would find their occupation gone if growers acted more as their own salesmen, for nothing in my opinion so checks the fruit-growing industry as the exorbitant charges for railway and market expenses. No wonder that some have given up growing fruit in their disgust when they find that after the whole year's toil and anxiety the returns are more than half taken up by deductions from the sale hill. I am fully alive to the fact that it is only a small minority of growers that live close to a large provincial town, and can, therefore, sell their own goods either direct to the consumer or to the town fruiterer, thereby saving both carriage and commission; but I should like to point out that land is at least double the rent close to towns for which it is going begging in rural districts. "Salesman's" principal objection to my advice is that relating to Apples, and I certainly stated that they are the sheet anchor of the English fruit-grower, and in spite of all he says about foreign or colonial competition being more severe than in any other fruit, I am every day more firmly convinced of the soundness of the advice I gave, and as a practical proof of that I plant more Apple-trees every year than all other kinds of fruit put together, and for this reason—no matter how plentiful

Apple-well, and my idea is, that if Apple-trees had half the care that is lavished on Grapes under glass, they would repay it at least double. It is not that we are exempt from foreign competition, as the barrels or cases are unshipped in eight of where I live; but no matter whether they are Gravensteins, of which "Salesman" writes so enthusiastically, they cannot compare with our home-grown ones, that are like a golden wax, streaked with crimson, and covered with a bloom equal to Grapes. Northern Spy and Baldwins do not succeed so well with me, but nearly all the other kinds enumerated come to great perfection here, and I cordially endorse all he says in their praise; in fact, it is not want of good sorts, but which to select from such excellent sorts, or rather to find space for them, that is the only difficulty I have with Apples. By-the-way, the Apple "Stirling Castle" (hero illustrated) is an excellent early and free-bearing kind, and does well in bush form. With regard to Peare, I am pleased to see that "Salesman" agrees with me, for I am more hopeful than he appears to be about the climate of this country in its most favoured parts, admitting of very excellent fruit being produced even in the open air, for in this locality Pitmaston Duchess is certainly as clear skinned and handsome from open bush-trees as they are in less favoured districts on walls, and the same with other good sorts, such as Baurré Superfin, Baurré Bosc, &c. Cherries are certainly a precocious crop, like Plums, for if you get a heavy crop, the chances are that everyone else has heavy crops too, and you find by the end of the season that you have not cleared so much as you have done from a light crop. Prices vary considerably, and with Cherries, the best paying crop, like White Heart, will be entirely spoiled by a spell of wet weather when fit to gather. For these reasons I never advise extensive plantings of either. Bush fruits are safe crops, very rarely failing, but the prices realised and expenses of gathering do not leave any great margin of profit, for it is only what is left over the cost of production that one has to look to for profit. Raspberries depend entirely on the suitability of the soil; it is too dry here for them. Strawberries are, in my opinion, different to any other fruit, for the immense quantity grown a few miles from here realise a high price, not because they are better than those grown in Kent and more inland counties, but because they are fit to gather at least a fortnight sooner, and it is on the first few pickings that the profit is made, for as soon as they are ripe in other parts we get cartloads hawked about at 1s. a gallon.

JAMES GROOM, Gosport.

3399.—**Work in orchard-houses, &c.**—It would be miserably unfair for a stranger to the garden in which the houses are situated to answer this question without more information than the inquiry contains. To give one instance out of many that could be advanced would be the possibility of giving an answer that would be fair, I may mention the water supply. If this water has to be brought from a distance, say fifty or a hundred yards, that would make all the difference in the labour—and hard labour too. Then, again, would the same man have to clean out the stove-holes, attend to the fires, and get the fuel ready? I may, however, mention that glass structures generally require a lot of labour, all through the spring and summer especially, and there is a great difference in the way in which they are furnished. One man will be wise in time, and limit the number of plants in pots according to the available labour, while another in his anxiety to please will grow double the number in the same space. I advise "X." to consult a disinterested and thoroughly practical man on the spot to give the information he

Apple "Stirling Castle."

imported Apples are, we can always sell home-grown ones at a higher price than the imported kinds are realising, and certainly our Apple-trees repay our care better than Vines or Peaches. I do not think the purchasers here are any different to other places; they certainly do buy the imported fruit, but in nine cases out of ten it is because they cannot get really good English grown ones, or they would not mind paying a price at which English growers could afford to grow their

the fuel ready? I may, however, mention that glass structures generally require a lot of labour, all through the spring and summer especially, and there is a great difference in the way in which they are furnished. One man will be wise in time, and limit the number of plants in pots according to the available labour, while another in his anxiety to please will grow double the number in the same space. I advise "X." to consult a disinterested and thoroughly practical man on the spot to give the information he

requires, or possible injury may be done to a deserving man.—J. C. C.

3398.—Grapes in a lean-to house.—A house with an eastern aspect is not a good one for Grapes, and I should not attempt to grow any variety of Grape-Vine in it except the Black Hamburgh. A west aspect is the best after south. Fairly good Black Hamburgh Grapes can be obtained from the house, and if it is well heated so much the better. Cement joints will do for hot-water pipes, or india-rubber rings may be used.—J. D. E.

— Yes, you may grow good crops of Grapes in a house facing due east if you utilise the sun-heat by careful ventilation. Such a house will want the ventilators open early in the morning, especially during the early summer months, when the foliage is rather tender, and the skins of the newly-formed berries liable to injury if the internal air gets overheated, and it will want closing early, according as the temperature declines after the sun has left the house. Three o'clock p.m., except in very warm, still weather, would not be too early to close the ventilators, and in the morning a little air should be given at the top of the house as early as six-thirty. If it is inconvenient to open so early you had better leave a little air on all night by opening one or two lights at eight or nine o'clock in the evening. With regard to heating, ordinary hot-water pipes and Portland cement joints will do very well, but expansion joints are better than cement. Forty-five degs. is a snitchie angle for the roof; indeed, for an east aspect it is better than a sharper pitch. For training the Vines place the wires 14 inches from the glass, or in such a case the leaves will get scorched.—J. C. C.

ROSES.

MARECHAL NIEL VERSUS CLOTH OF GOLD ROSE.

As to hardy-climbing Yellow Roses, there is no doubt that our gardens have suffered since the advent of Marechal Niel, for as soon as the latter was introduced everybody planted it and ignored altogether the Cloth of Gold Rose. In eight cases out of ten the Marechal is a failure in the open air—at least, it is a failure so far that it neither grows so vigorously nor flowers so freely as the other. I am, of course, aware that the character of the Cloth of Gold is somewhat "milfy"—that is, it is rather tender, and will only flower satisfactorily on a wall or building with a south aspect—het given these conditions, and budded on the Standard Brier as a stock, it is altogether a far more reliable Rose than Marechal Niel. I am free to admit that the Cloth of Gold is one of those Roses on which the cultivator must be prepared to exercise a little patience, as it does not make a vigorous growth until the roots have got well established in the soil. When the latter is provided with a fairly warm rest-run it frequently makes shoots 6 feet and 8 feet long, which, if insiled in their whole length, will produce a good number of flowers the following year. These blossoms, if not quite so fragrant as the Marechal, are superior both in size and form, and of that rich golden colour which once made it such a favourite. Seeing that the Cloth of Gold is hardy enough to live for twenty years on a pillar in an open but sheltered garden, no one need hesitate to plant it against a wall, as only in very severe winters does the growth of the pillar plant I have alluded to get injured by frost, and then only the soft green tops of the shoots are touched. It is very evident that residents in the North of England appreciate the hardy character of the Cloth of Gold, as an extensive grower of Roses in the West tells me that for several years past he has sent a considerable number of plants to different places in that part. These, however, have been all dwarf plants worked on stocks suitable for Teas Roses. From my own experience I cannot write favourably of the behaviour of these dwarf plants; but when they are worked on the common Brier as a dwarf standard I never knew a plant to fall if given a little time, and, so far as my knowledge goes, it is not subject to canker like Marechal Niel.

3414.—A Gloire de Dijon Rose.—has it not occurred to you that the bed of soil for the roots being on the boiler-flue is in a most

unsuitable place for any plant to grow? The roots must be often too warm, and in all probability too dry. You had better find a position away from the flue to make up a bed of soil for the roots, and put in a fresh plant at once. Should you be troubled with green-fly in future you had better dissolve two ounces of soft-soap in a gallon of water, and well syringe the Rose once a week. Femigating where there are Vines is attended with danger, besides being costly.—J. C. C.

— You are trying almost an impossibility when endeavouring to grow any Rose under such circumstances as you describe. A bed of soil upon top of a boiler flue, and then covered in by a frame, afterwards having efficient manure placed upon it to cause heating, is altogether against reason in growing Roses. They do not want such strong and uncertain bottom-heat, as your plant must inevitably often receive. I would strongly advise your giving up the attempt. Plant elsewhere, and if the roots must be outside give them the protection of plenty of loose straw. Treat them, in short, the same as your Vines, which, as you do not complain, I presume are doing well. Anyhow, you are trying far too many and varied subjects in the same house.—P. U.

3398.—Rose in a greenhouse.—Rose foliage does not scald very readily, even when against the glass. It is often difficult to avoid its touching, but I should certainly not try to secure its touching, as your adviser states. I much prefer the Rose-growth to be made the lower side of any wire supports, as the wood is easier to get at, and is then kept fairly away from the glass, allowing more air and better light around the whole.—P. U.

3413 — Marechal Niel Rose in a greenhouse.—Your plant is attacked with canker, either below or above ground, and you cannot do better than to root it out and put a young one in its place; but previous to doing so, take away some of the old soil and supply its place with fresh. Do not use much manure. A good heavy loam is what suits it best. I have no doubt you think it strange that your plant should fall so suddenly. That, however, is easily explained—when the flower-buds are forming the tax on the resources of the plant is the greatest, it is then that a sudden collapse takes place.—J. C. C.

— You have stated your difficulty very well and fully, except for saying whether the soil has been kept extra wet or allowed to become too dry. Either of these, as well as over-feeding with liquid-manure, would have just such results as you describe. Which is it? Or it may be that your plant is attacked by canker. If the latter is the case, you will find a warty protuberance where stock and Rose join, and your plant is of no further service. Seeing the plant is over the hot-water pipes, I am inclined to think the roots have been very parched some time recently.—P. U.

3387.—Rose disease.—A bad attack of mildew will sometimes cause the brown patches of which you complain. The mildewed spot appears to develop into a kind of canker. A little dry sulphur rubbed on the affected parts as soon as the mildew appears will prevent the injury. The Marechal Niel Rose is very subject to be attacked in this way, especially at the base of the flower-buds. I should lose many fine blooms every season if I did not watch for these mildewed spots and apply the remedy I have suggested, or a little liquid soft-soap applied with a brush.—J. C. C.

— What "Sufferer" complains of is so disease; it is simply the result of bad treatment. His plants, if under glass, have been kept in much too moist a atmosphere; in this case they will often rot and damp off as he describes. If it is the open air, untempered wood sometimes goes that way from frost. However, this last is very seldom; not so, unfortunately, with the young growth under glass.—P. U.

3375.—Manure for Roses, &c.—It would be somewhat difficult to decide upon the best manure without knowing the class of soil it was to be applied to. Roses like almost all or any manures, but which is most suitable depends entirely upon the soil. For light soils, heavy and close manures, whether of natural or artificial composition, must be used. For a sample, say your soil is light and sandy, then do not use soot or wood-ashes, nor thoroughly dry stable-manure from a spent Mushroom or Cucumber-bed. If heavy, use manures that will

tend towards making it lighter. Cow, swine, and all animal manures are good for light soils; so, too, is a light-soil, when well intermixed with decayed weeds or vegetable refuse. Guano, crushed bones, and all manures are good; but, as previously remarked, it depends on the soil.—P. U.

— I have used the native guano for Roses, Gladiolus, and many vegetable crops with the best results. It promotes a steady and not too luxuriant growth, which shows that it retains its fertilising properties for some time, but there are others perhaps equally as good; at the same time there is nothing equal to stable or farmyard manure. I applied a dressing of rag-manure—this is the refuse from a mill where rags and old carpets are worked up again for other purposes—four years ago to one part of my garden, and I still find some of it present in the soil. Roses, fruit-trees, and other crops like it, as is evident by the presence of roots where any of the stuff is found.—J. C. C.

— An excellent manure for Roses is Clay's Fertiliser. It is sold largely, and must be used carefully according to the directions. The great thing in using artificial manure is not to overdose the plants, otherwise they will suffer injury.—C. T.

— One of the best manures for Roses is made from sheep-droppings. These are collected and put into a tank or barrel (sunk in the ground), which is then filled up with water and allowed to stand for some weeks. The liquid is then dipped out and used with a certain admixture of pure water, according to its strength, about twice a week. Well rotted pig or cow manure is also used for digging in at the roots of Roses, often with very satisfactory results.—A. G. SMITH.

3403.—Rose "Her Majesty."—Your plant of this Rose will produce more flowers if you do not prune, or at the most only to cut off about 3 inches of the young shoots every spring. I have a plant trained to a pillar which gave me several early blooms last year, and two or three more in the autumn. This Rose is subject to mildew under all conditions of growth, and I regret to tell you that I cannot tell you what to do to destroy it more than you have already done, except you paint the stems now with the mixture you are in the habit of using.—J. C. C.

— Grand as this Rose is, it is a most disappointing one. No variety is more subject to mildew, and few flower less freely. Peg down any long shoots and do not tend too liberally. Bottle against mildew from the first, using the remedies so frequently recommended in these pages.—P. U.

3372.—Roses on Brier cuttings.—Roses are grown just the same on this as upon any other dwarf stock, say, the De la Grifferaie, Manetti, or Sooding Brier. The cuttings of Brier should be made up in September or October, cutting the ripened wood of the same season into lengths of about 9 inches to a foot. Insert these firmly three-fourths of their length in the ground, and about 2 inches to 3 inches apart in the rows. Next autumn lift and trim the stocks, afterwards planting them out 1 foot to 2 feet apart in the rows, according to the strength the variety of Rose you intend working upon them possesses. In planting the stocks do not cover the bottom part more than 2 inches. It is necessary to bud as close upon the base of the stock as possible, in order to avoid any suckers from dormant Brier eyes. Make the Brier-cuttings similar to the Currant or Gooseberry. They strike root more freely if planted deep, and by lifting them and replanting you save much annoyance as regards suckers, besides facilitating deep budding.—P. U.

— Briers from cuttings when strong and well-rooted make very good stocks either for budding or grafting. So far as regards open-air culture, budding is the proper method to adopt, and this should be done in July or August, the bud being inserted close to the ground or even a little below the surface if the weather is hot and dry, as by the removal of a little soil moist bark that will work freely can generally be found. The usual way of raising Brier-stocks from cuttings is to plant the cuttings in the autumn in rows somewhat thick, as all will not root. Give one season's growth, and the following autumn lift, remove latent and other buds from the base, and plant in nursery rows 2½ feet to 3 feet apart, and 1 foot apart in the rows. The land for Brier-stocks must be good, so as to get strong growth, as the bark on puny stocks always works abnormally. In planting out the rooted cuttings keep them up as much as is consistent with free rooting. If planted deep there is not quite so good a chance of getting the bud quite so close to the roots.—E. H.

OLD HOUSE AND SURROUNDINGS.

The annexed illustration represents a beautiful old house surrounded by a garden of quite an unconventional type, and is the property of Sir George Wemhwell. The building shows one part of the original hall inhabited by the Colvill family, who lived there at the time of the Norman survey. Such specimens of pure old English architecture are now so rare that peculiar interest attaches to them apart from the historical associations that are generally connected with them. The quiet colour of the weather-beaten and Lichen-stained old walls is enhanced by the luxuriant trees and shrub growth that reaches almost to the doors and windows, and this is one of the chief differences between old and modern country mansions. Old houses almost invariably nestle peacefully amidst unrestricted tree-growth; new ones, as a rule, stand on a treeless level, often amid a maze of pattern beds and gravel, and are rarely accompanied by a raised terrace, with its excessive array of statuary and other formalities. We fear that architects, not landscape gardeners, are often responsible for this state of things. They seem to have an abhorrence of greenery of any sort approaching their handiwork. The prevalent practice among architects

bright and green in summer by using the bedroom slops upon it without any expense.—J. C. C.

— Diluted bedroom slops have a certain value, and might be more often utilised, but they are not equal in fertilising power to the best artificials which can be used without creating the least unpleasant smell. A tablespoonful of guano or nitrate of soda in a gallon of water will be profitable if any stimulant is required, as would also blood-manure, Ichthemic guano, and Clay's Fertiliser. In actual practice there will always be a certain amount of trouble and difficulty in collecting and applying bedroom slops, and my experience has been that without personal supervision is given, the chamber slops are more likely to be cast down the drains than used in the garden.—E. H.

— I do not think you would find the bedroom slops at all a safe or satisfactory substitute for other liquid manures. It would vary so much, and as you do not possess a tank in which to make a good mixture, it would be much more trouble than it is worth. Liquid manure made from guano would not be half the trouble, while it is much more agreeable and safer. Use it at the rate of three-quarters of an ounce to a gallon of soft water. If soft water

dose to kill them outright. To test this matter, I advise you to give a few cuttings of the double varieties to some friends and let them grow them to see if there is any difference in their behaviour under the treatment of others. With regard to the maggots of which you complain, it is evident your soil is infested with them. In future I advise you to make the soil before using it by placing it in a moderately warm oven for a couple of hours.—J. C. C.

3381.—Creeper for a chalk bank.—The best creeper I have seen on the chalk banks at the south coast railway stations is St. John's Wort (*Hypericum calycinum*). This has covered several of the slopes most beautifully, and always looks well. It is evergreen, and for a long period bears immense quantities of deep-yellow flowers, beautifully set in green foliage.—P. U.

— I should recommend a combination of Speedwell, Creeper Jenny, and the various forms of Stonecrop; the smaller *Ferulifolia* would also probably do well, but do not try the large variety, it is too smothering.—A. G. BUTLER.

3410.—Christmas Roses.—Varieties like *Helleborus atrorubens*, for instance, rosy pink, with long flower-stems, the flowers of which droop a little at all times, will not last fresh beyond a few hours in water when cut, owing to a weakness of the stem near to the flower. Nothing will prevent such as these flagging, I might say prematurely. The variety *H. niger*, the common Christmas Rose, is the one alluded

OUR READERS' ILLUSTRATION: Old house and surroundings. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. Fowler Jones, Quarrybank, Malton.

now seems to be that of raising the floor line of their houses seldom less than 2 feet above the natural ground level; consequently, the surrounding soil has to be made up to it at great expense, or you get the alternative of the conventional terrace, with more or less steep bank having no connection with the outlying ground. It is, therefore, a great pleasure to come upon such a house as that here represented after visiting those of the modern stamp. One can picture to one's-self the charms which the old garden in connection with such a house must present at every season of the year. It would be brilliant with flowers in spring, shady in summer, glowing with the rich hues of the decaying leafage in autumn, and sheltered and snug-looking in winter. G.

3384.—Fowls in a garden.—Bring an action in County Court against the owner of the fowls for damage done. See former reply, 3rd December, page 562.—O. T., &c.

3391.—Liquid manure.—In the absence of anything better, the slops to which you refer are useful, but the difficulty is to know to what extent to dilute them. The mixed slops would perhaps require one-half of clear water added. Urine alone requires ten parts of water, and both should be kept in some vessel in the open air for a week or ten days previous to use. May a poverty-stricken suburban wren might be sent

is not available let any other water stand in the air for a few hours. If you mix up, say, a pound of guano in a gallon of water and use a sixteenth of this to a gallon of other water, previously stirring the solution, you can have liquid manure to hand always, and undoubtedly in a much pleasanter form.—P. U.

— Even bedroom slops ought to be kept for a time in a tank before they are used in a diluted condition, though for Fancies I have used them in a fresh state without injurious results.—A. G. BUTLER.

— Certainly, there is nothing better. For plants in the open ground there is no necessity to dilute bedroom slops, &c.; but for pot plants an equal quantity of water should be added. In any case it is advisable to expose anything of this kind to the action of sun and air in an open tank for a day or two before using it.—B. O. R.

3415.—Double Fuchsias, &c.—I cannot help thinking that there is some mistake in this case. Occasional instances of reversion from double to single flowers are not uncommon; but if the facts are as is stated in the inquiry it is quite of an alarming character, and opposed to all previous experience. One requires to have fuller information as to past treatment before an opinion can be formed. Have you been in the habit of giving the plants strong stimulants? I hardly think so, as no plant sooner recovers excitable fertilisers than the Fuchsia. I have known a moderate application to cause all the leaves to fall from the plants, and a powerful

to by "V. B." The flowers are pure white, erect, very freely produced, and exceedingly useful in a cut state. Blooms of this will last longer in water if the end of the flower-stem is slit upwards an inch or so long; a greater surface is exposed for absorption of water by this means. The first named is useful for the decoration of the borders.—S. P.

— The reason is that the flowers of the Christmas Rose, as you call them—but which are really the Lenten Roses, varieties of *Helleborus orientalis*, aboriginal, celobious, &c.—require to be actually immersed in water at least once a day. They quickly flag when merely placed with their stems in water like the ordinary *H. niger*. Try this plan, and I think you will find that it will answer. Until I did this I could not keep the blooms at all fresh. The nodding, quietly-coloured flowers are very pleasing in a large bowl. The flowers of the Christmas Rose will last well; but there is greater substance in them than in the *Helleborus* that bloom at this season.—C. T.

3380.—Ants.—These are very troublesome in plant-houses, especially when they are in the Orchid house, as they dirty the flowers often. A very good plan to get rid of them is to cut Apples in halves, remove a portion of the inside, so as to make a little basin, and lay them about in the places where the ants congregate. Look

at the hits of Apple vary often, and you may catch large numbers in this way. Even hollow bones have been found useful, and it is an easy matter when everrun with nuts to dip them in boiling water. This will prove an effectual remedy, and another commoner plan is to put some treacle and moist sugar into a bell-glass, damping the latter, and they will be enticed to the trap, and may readily be got rid of. Small pieces of sponge soaked in a sweet substance are also good traps.—C. T.

INDOOR PLANTS.

3394.—**Culture of Pelargoniums.**—The old-fashioned show Pelargoniums are not nearly so well grown generally as they were about thirty years ago. The reason for this, they have gone out of fashion and are thus neglected. In the old days a house was usually given up to them, and in its arrangement of etages, &c., the plants were placed in the best possible position for making sturdy growth. A light, moderately warm, sufficiently ventilated house is essential to do them well, and with proper convenience in this respect, and some good holding loam freely enriched, there should be no difficulty in growing good, well-hooped specimens; but, at the same time, it does require a considerable amount of skill to have them really on any particular day for the exhibition tent. It will take three years to grow a fairly good exhibition Pelargonium, say, a yard across, but when the framework of the plant has been obtained it is quite possible to keep it in good condition for several years. As a rule, a yearling plant may be bloomed well in a 5-inch pot. When the flowers fade the plants are placed in the open air to ripen, less water being given to assist the maturing process. About the end of July or first week in August the plants are out down to within a couple of eyes of the base, and are kept dry till the eyes start away. When the young shoots are an inch long the plants are shaken out and repotted in clean pots usually of the same size. In winter they are kept on shelves near the glass in a warm greenhouse, with a night temperature of 50 degs. or so. Watering all the winter must be carefully done, keeping the roots generally moist, but not rashly using the water-pot. In January or February shift into the flowering-pots, which may be 8½ inches to 7 inches in diameter, according to size and vigour of plants. Use rough turf compost, and pot very firmly. I always think Pelargoniums require to be potted as firmly as hard-wooded plants. Commence training in good time by opening out the shoots, either by linking them down to the rim of the pot or by placing in a few small stakes. Use the syringe freely on fine days in spring, but always have the foliage dry before night. Fumigate in anticipation of the flies, and give liquid-manure when the pots are filled with roots. The second year the plants will require larger pots, but otherwise the treatment will be the same.—E. H.

— These are so easily cultivated that the treatment must have been wrong if they are not doing well. Established plants after flowering need a season of rest. They are kept comparatively dry at the roots, and may be placed in the sun out-of-doors in June and July. Cut them down in August when the roots are quite dry; this prevents bleeding from the cut portions. Water them in two or three days, and they will start strongly. I leave them out-of-doors until the shoots have grown an inch or two, and they are after that taken in to be repotted; the roots are greatly reduced, so that the plants can easily be repotted into a size smaller than they were growing in before. The plants when growing should be placed near the roof glass of an airy greenhouse, and they must be kept clear of green-fly by fumigating and from mildew by dusting with dried flowers of sulphur. The potting-soil should be formed of four parts loam, one of leaf-soil, and one of decayed manure.—J. D. E.

3411.—**Arum not flowering.**—The treatment has evidently not been right; in fact, it was wrong to out them down. When the leaves die off they must be removed, but at no stage of the plant's growth should be out down. The summer and autumn is the time for the plants to make their growth. I encourage them to the open air in May, and as soon as they are established plant them out in the

open garden. They like plenty of water, and to make sure they are not neglected, I plant them in Celery trenches. They will make strong, vigorous plants, and are but little trouble. Dig them up and replot them in September, when they will speedily begin to grow freely and produce flowers abundantly during the winter and early spring in a warm greenhouse. They like rich, open soil, and plenty of water when growing.—J. D. E.

— These plants should never be out down nor yet dried off. Keep them growing all the year round, if possible—in summer with rich soil and plenty of water, and during the winter in a moderate warmth, and they can scarcely fail to flower well. I always find that after having been planted out-of-doors for the summer (in rich soil and kept well watered, of course) and lifted and potted at the end of September, they burst into bloom almost directly with the aid of a genial warmth and continue to produce flowers at intervals until late in the following spring. Do you give them water enough?—B. C. R.

3393.—**Cyperus alternifolius variegatus.**—This is a delicate or "miffy" subject, and requires very skillful culture to do well. I think it grows best in sandy loam and peat, and it should be kept in a mild stove or intermediate house, with a constantly humid atmosphere, light shade, and a regular supply of water at the root. Try watering it with a weak solution (half an ounce to the gallon) of nitrate of soda once a month.—B. C. R.

— This plant requires rather lighter soil and better drainage than the green-leaved form. Probably your soil is too heavy; try rough sandy peat and leaf-mould. If the soil gets sour the leaves will die off in the way described.—E. H.

3408.—**Gloxinia seedlings.**—If the pots the plants now occupy are becoming filled with roots they should have a moderate shift at once, say into 3½-inch or 4-inch pots, as growth will now be more active. Use a mixture of peat, loam, leaf-mould, and sand, and drain well. Keep the plants on a shelf or high stage near the glass in a moderately warm and constantly humid atmosphere. The temperature of a cool stove suits them well at this season. Give a free supply of water as soon as the roots are fairly at work again, and when sufficiently advanced, shift the plants into 6-inch pots. In these they will bloom well, especially if some weak liquid-manure is afforded once or twice a week after the roots have filled the pots. Shade lightly from direct sunlight at all times, and ventilate moderately in mild weather only.—B. C. R.

3390.—**Choice Primulae for show.**—The method suggested—that of keeping the plants over till the second year—is undoubtedly the way to get large plants and an abundance of bloom, but the plants are not so shapely as those from seed down the first season, and if sown in March they can be got 18 inches to 24 inches across by November. You should pick all the flowers and buds off some of the best of the plants now in bloom, selecting two or three times as many as you wish to exhibit, as all will not do equally well. After giving them free ventilation remove them to a cold frame, matting up well on frosty nights. At the end of May remove them to a lightly shaded position out-of-doors, and always keep moist. About the end of June replot them, and when established and growing give them a shift into 8-inch or 9-inch pots, and you will have glorious masses of bloom presently.—B. C. R.

— Many persons grow Primulae the second year, and exhibit them successfully; but they are often beaten by those who grow them well from seed the same season. It is easy enough to grow two-year-old plants. Keep them near the glass after flowering in a heated greenhouse, and turn them out into ordinary garden frames in May. They pass through a sort of resting period at this time, requiring but little water. Replot them about midsummer, and grow them on in the same way as seedlings of the current year. I would grow some both ways, and see which are best.—J. D. E.

— When Primulae are sown early in February, and grown steadily on, they will reach a large size by November. Still, if Primulae are treated in the same way as Cyclamens usually are now—i.e. the seeds sown as soon as ripen in June, and the best of the plants

selected for growing on—they will, if well done, make very large plants in 7-inch or 8-inch pots by the second autumn. When very fully developed plants are required, I have sometimes pinched the flowers off the late-sown plants and kept them growing all the winter. The same thing is sometimes done with Double Primulae when very large specimens are required for a particular purpose. Still, this does not alter the fact that very useful decorative stuff can be grown in fine seasons from seeds, and though it may seem a wasteful method, I believe the majority of cultivators do throw the old plants away and raise young plants annually. Plants which have exhausted themselves by flowering, and possibly also by seed bearing, lose colour and are not always so useful as young plants.—E. H.

3404.—**Asparagus plumosus.**—Seedlings are much more easily raised than plants from cuttings, and they grow and do better in every way. Sow the seed in heat, and grow the plants on quickly in a cool stove temperature, with abundance of moisture both at the root and in the atmosphere. The difference between the ordinary *A. plumosus* and *A. p. nenus* is not great, the latter being merely a selection of the most compact growing form. Even the latter, if planted out and heated liberally, will "run away" sooner or later, and for cutting I should prefer the larger form, as it grows more quickly and strongly. Train it on wires near the glass.—B. C. R.

3395.—**Azaleae after flowering.**—When these have finished blooming "Beginner" had better first pick off the seed-pods, or these will draw much nourishment from the plants. The next question is—do the plants require fresh potting? As a rule, amateur overpot Azaleae. Unless badly drained, or in very small pots, they will only need a dressing of pure peat-sole—say half an inch deep in a 32 sized pot carrying a fair-sized plant. Keep them in a warm and moist greenhouse temperature, frequently syringing them overhead, and taking great care that they do not suffer from drought. This point will need close attention, because the root is very deceiving. I would prefer them to go out-of-doors for a short time in the autumn, as the air and dews help them so much. Do not bring them out too suddenly, nor stop their genial treatment until the growth is somewhat developed. From the early part of August until the middle of September they will be quite safe out-of-doors. Azaleae do not mind a cold night so long as their growth is matured, and no more than three degrees of frost touches them; in fact, cold, dowy mornings help them very much at this latter stage.—P. U.

3382.—**Treatment of Azalea mollis.**—These always produce the healthiest young growths from just under the flower-trusses, and unless the flowering-shoots are very long and straggling I would not advise your cutting them back. The earlier growth is made and matured the better will be the results next season. Keep the plants in a genial atmosphere until June. Amateurs seldom study Nature sufficiently, and do not bear in mind that the time such forced plants are out of flower must naturally correspond with warm summer weather outside. Yet they frequently neglect to afford their plants anything approaching natural treatment after their first flush of beauty is over. Any plant that has been excited into bloom prematurely must not be turned into extreme cold while still in full growth. You should afford them ample protection until the end of June, when they may be planted or plunged out-of-doors in a warm border. Here the growths will mature and set flower-buds for next season. These satisfactory results cannot possibly be obtained if the plants receive a severe check directly after flowering is over and much young growth is active.—P. U.

3317.—**Primula obconica.**—Pieces of the old plants may be potted singly and grown on as before, but such divided plants never do so well as seedlings. The best sort for this species is a nice, free, or sandy loam, with a third each of leaf-mould and old hot-bed manure; if the loam is at all rough or coarse, add a little peat. Drain the pots well and make the soil firm. It succeeds best during the winter in a light and rather well ventilated greenhouse at 45 degs. to 55 degs., but in summer a cool and shady position outside must be given it. Keep the soil always moderately moist.—B. C. R.

ORCHIDS.

BEST WINTER-FLOWERING ORCHIDS.

Ceologyne cristata.

This plant (flowers of which are here illustrated) is now too well known to need much description. It is a magnificent Orchid for winter blooming; it should be grown in a cool stove, and in the autumn placed in a little extra warmth to finish up the bulbs and induce them to push out their racemes of flower, which in the sepals and petals are pure-white, stained in the lip with orange. There are now numerous varieties of this species which differ more or less in the breadth of sepals and petals, that known as the Chatsworth variety, sometimes called maxima, being the best. In the variety Lemoniana the flowers are broad, as in the Chatsworth variety, but the lip, instead of being broadly stained with yellow or orange-yellow, is of a faint pale yellow;

flowering plants should be taken into a cool-house with a dry atmosphere. Here they may be allowed to remain all through the season, and until the young shoots again show signs of life, when the plants should be removed to warmer quarters and a moister atmosphere. It is an Orchid which I used to grow in quantities upon blocks of wood, and in the temperature of the cool-house all the summer, keeping them nearly quite dry; and I used to flower them freely in or about the month of April or May, but I found if they were too late in the season before the flowers appeared, that they did not last long, but they were soon past and gone, and that plants that flowered early in April lasted in bloom better. The culture of Orchids upon blocks of wood, as used at the present time, I do not like, because I do not think it is congenial; but in the place of blocks of wood, I recommend the use of small earthenware pans or baskets, and into one of these plant the

her plants of it are now flowering beautifully. She has three plants bearing nine spikes of blooms, one of which she sends me, and hopes to see a note of it in GARDENING, and she adds "it ought to be grown by everyone having a stove." This last statement I heartily endorse, and I have often wondered why persons with the accommodation of a stove-house do not grow many of these small growing Orchids. *Angraecum citratum* was first brought home from Madagascar now nearly thirty years ago by the Rev. Mr. Ellis, and it first flowered with Messrs. Veitch of Chelsea, and it remained a scarce plant for some years in our collections, but the Messrs. Low now have a great stock of it flowering beautifully; but I noticed when recently at their establishment the numbers were considerably less than they were some two years ago, so that the plant has evidently been drawn upon largely. I remember Mr. Ellis telling me that this Orchid is very common in its native country, and that the flowers are much used by the natives for personal adornment. It grows in the coast-line, that portion of the country which is so inimical to the health of Europeans, and is found upon the under shrubs, always in the shade. Here it abounds; but from the fact of its being a small plant, and that it is always being in a wet condition, it has been hitherto found a somewhat difficult plant to import in a good condition; but yet we have now got it well established in this country, and it is fairly reasonable in price. This plant should be well drained, and planted in living Sphagnum Moss, carefully removing any that becomes dead or sour, for although it likes an abundance of water, nothing of a dead or sour nature must lie about its roots. Place it in a small hanging earthenware pan or basket, and place it in such a position where the sun does not shine upon it; yet I have observed when exposed to the influence of the light the flowers come much whiter than the plants in the shade. The raceme is about 6 inches to 9 inches in length, the flowers being dense, and furnished with a long slender spur. They are white with a pale straw colour pervading them; but in the deep shade they are of a dull citron-yellow, which is their colour at home in their native home. I have found it to revel in water during the summer months; but I have always kept it well drained, and during the winter, although a considerable reduction is necessary, the plants must be kept nicely moist.

MATT. BRAMBLE.

Flowers of *Ceologyne cristata.*

whilst in the variety *alba* they are of the purest white, without a spot of any colour. It is found growing wild in Northern India at an elevation of 5,000 feet to 8,000 feet. M. B.

DENDROBIUM CAMBRIDGEANUM.

It is now over sixty years ago since this plant first flowered with Sir J. Paxton at Chatsworth. It had been gathered the year before by Mr. Gibson when collecting plants in Northern India for the Duke of Devonshire. A flower of this Orchid is sent me by "Nemo," of Glastonbury, for a name, who states that he has a small plant with thirty blooms, for which he may be thankful. The rich, golden-yellow flowers, with a deep, velvety, blackish-purple blotch at the base of the lip, will make the house gay and cheerful for a short time. This plant, which is more correctly named *D. cobretatum*, is one of the kinds which flower from the young growths before they are fully matured, and with the green leaves upon them; and after

Dendrobium Cambridgeanum, drain it well, and use for soil peat-fibre of the best quality, mixed with some living Sphagnum Moss, and do not disturb it, for it is a plant that does not like removals, but resurface it when necessary. Do not urge it to grow by the use of artificial manures, or anything of the kind, for I have observed that when the plants grew too vigorously they do not flower so freely.

MATT. BRAMBLE.

ANGRÆCUM CITRATUM.

From time to time I am surprised by some of my readers sending me blooms of plants which I should not have thought of recommending to their attention, and this is one of them, not because it is not a beautiful species, but because it takes a great deal of attention, and likes warmth and moisture all the year round, and would not be showy enough to please the majority of growers. But here I have flowers of this plant from one "Bessie Lookwood," saying

DENDROBIUM LUTEOLUM.

SOME flowers of this plant came to me from "Jane Beckett," who says a friend gave them to her, and told her he had brought them from Rio. She asks for the name, and wants to know something of its treatment? Well, in the first place, I think "J. B." must have fallen into an error in making the assertion that her friend told her he had brought this species from Brazil, because there are no *Dendrobiums* in that country. Labels are very easily transferred either by accident or otherwise, and if a person is not acquainted with the distribution of genera and species it leads to an awkward episode. Now, for instance, this *Dendrobe* comes from Burmah, whence it was introduced by the Messrs. Low, of Olispton, with whom it first flowered in the spring of 1864, or nearly thirty years ago. The plant has slender, erect growth, bearing deep-green leaves, which are persistent until after the flowering season is over. The flowers are produced on short racemes, usually in pairs; sometimes, however, these are produced together, and I have seen even four borne upon one raceme. These are about 2 inches across, and of a pale yellow or soft primrose colour, faintly streaked with red on the lip, and of a pleasant fragrance. Besides this, the typical plant, there is a variety called *oblongocentrum*, which does not differ much, but it has some greenish, short, woolly hairs on the centre of the lip, and there also a stain of orange colour. Both plants thrive under quite the same treatment. It should be grown in hanging baskets, which require to be well drained, and the plants should be well exposed to the sun and light, shading only from the hottest sun through the middle of the day; and it must be kept well supplied with water, both overhead from the syringe and also to the roots. They should be potted in a mixture of good brown peat-fibre and chopped

Sphagnum Moss, but not too much of it, for I find this plant to grow for the best when extra well drained and with but little soil about its roots. As the growths ripen the plants require to be moved to a cooler position, where they may be dried off and rested, but by no means allow the bulbs to shrivel, or you may have great difficulty in restoring them; but having nursed them through the winter with care restore them to their summer position about the beginning of the year, and about this time, or even later, the flowers will appear in great abundance. I think this is about all I know of *D. luteolum*, and though it cannot lay claim to being one of the showy species from this land of Dendrobiums, it may fairly be called a very pretty and a most interesting plant, and it flowers, too, at a very dull time of the year.

MATT. BRAMBLE.

DENDROBIUM LINAWIANUM.

HERE is an old plant which was first introduced to our gardens just upon seventy years ago, and in spite of the number of plant-collectors that have traversed the East, no one appears to know the exact spot from whence it comes. It is said to be a native of China, but that is a large country, and in days gone by no one would be able to reach some parts of the country that they can now. The plant, from being said to come from China and Japan, was confounded by Lindley with, and named by him, *D. moniliforme*, and under this name it was abundant in collections in my younger days, when it was much prized for its beauty and for its early flowering. In growth it much resembles *D. nobile*, but the bulbs are more compressed and flatter, and I am asked by "J. Macfarlane" to tell him if it is a *nobile* without the spot at the base of the lip? Here again is another instance of the long life of Orchids, the species in question having never been known to have been imported but once or twice, and that some sixty years ago; but we have plenty of it growing in our gardens to this day, and growers too that do not know it when they see its flowers, these being borne in twos and threes together on a short erect raceme. They are of a rosy-lilac or cerise, the centre of the lip white, and having two crimson spots near the centre. I have had this species blooming at Christmas, and also in the month of May, but not from the same specimens; but from plants that had been purposely retarded the May flowers were produced, whilst the earlier ones were borne by plants that had been forced. This plant is much like *D. nobile* in general appearance, and yet one can easily pick it out from amongst the last named, and it thrives well under exactly the same treatment. *D. moniliforme* is now in cultivation. It is a small white-flowered plant, not nearly so handsome as this species. A very pretty hybrid from *Linawianum* I saw exhibited in the Drill Hall, Westminster. It was called *Burfordiense*, and it was really a charming thing, and I hope to see it again.

MATT. BRAMBLE.

3325.—*Saccolabium Blumei*, &c.—*Saccolabium Blumei* decidedly requires stove treatment, accompanied, however, by plenty of ventilation. This plant grows in thousands on the trees surrounding the Rice-fields in Burmah. During the rainy season the Rice-fields are under water, and irrigation is continued until the Rice ripens, about December, when the water is run off. The evaporation from these fields of water leads the air with moisture, so that with the heavy rains and humid air the plants are kept in full growth up to December; they then pass through a very dry season until the first showers fall, about the end of March. There are, however, heavy dews at night during the dry season, which keep the roots plump. Plenty of water and heat during the growing season and moisture in the air in winter are the best for them. On no account, however, must the leaves be syringed in the winter; the air must be kept moist by damping the floor of the house and stages. This plant does not like the roots disturbed. If the potting material gets sour it should be picked out, and fresh moss, mixed with broken crocks, should take the place of the old material. On no account should peat be used in potting this class of plants. *Dendrobium album*: This plant growing in quantity on the coffee bushes of the deserted Coffee plantations at

Wella-ghaut, west coast of India. Here the rainfall is enormous—during the rains often 10 inches a day, the annual rainfall amounting to 650 inches. In consequence of this enormous downpour all the Coffee plantations on Wella-ghaut have had to be abandoned, and the roads being overgrown and the country infested with wild elephants, it is very difficult to get into it to collect the plant. This plant therefore requires great heat and moisture during the growing season. During the dry season, January to March, the plant is exposed to the full rays of the sun and loses all its leaves, starting in growth again with the first shower in March.—E. S. BERRELEY, *Speicheley-Bitterne, Southampton.*

FERNS.

HARDY FERNS IN PLEASURE GROUNDS.

IN most gardens there are situations which, owing to perpetual shade through buildings or trees, are found extremely difficult to embellish satisfactorily. Places of this description occur frequently in the neighbourhood of the dwelling-house, and are often a source of vexation, as the majority of flowering and fine-foliated plants will not thrive therein. For such localities hardy Ferns are the most suitable occupants, inasmuch as the same conditions which prove so fatal to the well-being of the majority of ornamental plants are just those

the occupants fail to obtain that luxuriance which constitutes one of the greatest charms of the Fern tribe. Although something in the way of hurra, stumps, or sandstone is necessary to keep the soil open, yet this kind of material should be introduced merely to effect that purpose, leaving as great a bulk of mould as is consistent with good drainage. The cheapest material that can be employed is the rootstumps of trees. They are admirably adapted for the purpose, and not only serve to efficiently drain the soil in which they are placed, but appear to retain in themselves a certain amount of moisture, even in very dry weather. Root stumps are often objected to on the ground that they ultimately rot away. That is, however, no detriment in the present case, as by the time they do so the plants will be well established. As regards soil there is no necessity to be particular. If some turfy loam or rough peat can be easily procured, the Ferns will be benefited by an admixture of it. Ordinary garden soil, with some of the roughly sifted portions of the refuse heap, will meet their requirements. No garden can be considered properly furnished without Ferns of some sort, and many a dark, dingy corner may be simply and almost inexpensively beautified by them. Where winter verdure is desired, the evergreen kinds need only be employed. In a general way, however, they should be used with the deciduous ones, as they contrast so beautifully when hurrying into growth in spring. T.

Royal Fern and Male Fern in the garden at Killeger, Killshandra, Ireland.

which enable them to maintain themselves in health and luxuriance. The construction of a fernery is often supposed to entail a considerable amount of labour and expense, and it is in this consideration which deters many from undertaking the culture of hardy Ferns. The Fern tribe is a large and varied one, and if it is desired to cultivate a large variety, then undoubtedly a good amount of forethought and care will be necessary to ensure success. There is, however, a considerably large class which is really hardy in every sense of the word, inasmuch as they will thrive in almost any situation, and require but an ordinary amount of care to be taken in planting. Amongst these are fortunately to be found great variety and exquisite beauty; they are, therefore, all that can be desired for our purpose. Many varieties of *Lastrea*, *Asplenium*, *Scolopendrium*, *Polypodium*, and the Royal Fern will flourish in the most ordinary garden soil, and can hardly be excelled in elegance of form and diversity of growth by the more tender kinds. They may be easily procured at a cheap rate of any nurseryman, and some of them, such as the common Polypody, the Male and Lady Fern, are generally plentiful in moist hedgerows, from whence they may be safely removed in early spring before growth commences. These varieties are mostly strong growers; they should, therefore, be planted so that they are not crowded in the way of nourishment. Ferneries upon a small scale are apt to become dried up in hot weather, and

3302.—*Phlebodium aursum*.—This Fern, when it gets into bad condition, takes some time to work round. Warm-house treatment would suit it better. The old discoloured leaves may be cut off; but the plant is a true evergreen, and the green leaves should be allowed to remain till the new growth starts away.—E. H.

3377.—Treatment of Carnations.—A great deal depends on the culture the plants receive as to whether the flower-stems will be stout and carry the flowers up well, but much more upon the variety. Some sorts have weak peduncles—too weak to carry the flowers erect, consequently they hang down. Many raisers of seedlings have merely an eye to obtaining good single blooms for exhibition, and make habit and constitution a secondary consideration only; but this is not what the general public want. Seedlings ought not to be raised either from weakly-constituted varieties or from weak-stemmed sorts that cannot hold the flowers erect. Sorts that hurt the only badly should also be discarded. A few of the best border Carnations to grow are Germanias, Purple Emperor, Mrs. Muir, Rose Celestial, Emma Lakin, Ruby, and Mary Merris amongst selfs. A few of the best flaked and bizarres are Robert Houlgrave, Joseph Crossland, Rifeman, Edward Rowan, William Skirring, H. R. Meyer, James Douglas, Mayor of Nottingham, Matador, Thalia, Sybil, and Jessica.—J. D. E.

The best plan is to grow the plants from the cuttings or layers always, in the open ground without any protection whatever. By this means strong, stocky plants are produced with stout stems and blooms, which rarely burst their stems.—A. G. SUTTON.

THE KITCHEN GARDEN.

3383.—**Vegetables for show.**—The following will make a good selection of eight varieties (Cucumbers should not be grown in a collection limited to eight varieties): Tomatoes, Peas, Cauliflowers, French Beans, Potatoes, Onions, Carrots, Turnips, Vegetable Marrows, and Cabbages. I have included ten varieties, as it is just possible one or two of the others may not be in first class condition on the show day. I should attach more importance to having first-rate samples than any particular variety; for instance, a first-rate Cabbage or Vegetable Marrow may carry more weight than very inferior Cauliflowers or badly-grown Turnips. Whatever is shown should be as good as can be grown, and a common variety really at its best is of more value in a collection than anything looked upon as choice at its worst.—E. H.

The two kinds mentioned, Tomatoes and Cucumbers, will do very well to be included in a collection of eight; but is the collection limited to eight kinds or eight varieties? because if the word variety is used two dishes of distinct varieties of Peas may be exhibited, or a dish of kidney and a dish of round Potatoes; but in a collection of eight varieties even, the greater number of kinds exhibited the better. I would show good Marrow Peas, Potatoes (a good white kidney), Cauliflowers (three good heads in a dish), good intermediate Carrots, and Onions from autumn-sown seed. Dwarf Kidney Beans always tell well when exhibited in good condition. Scarlet Runners and Broad Beans may be grown for extra.—J. D. E.

—In addition to Tomatoes and Cucumbers the following should be added: Potatoes, Peas, Onions, Cauliflowers, Carrots, and Globe Artichokes.—S. P.

3271.—**Good King Henry.**—I have a bed of the above growing in my garden that has been planted over 20 years. It is planted 16 inches apart each way. I notice that J. D. E. advises it to be planted only 9 inches apart, but it is impossible to grow good roots so close together, as some of mine are over a foot across by the time the shoots are ready for use, and I think it is the most useful and profitable early vegetable we have in the garden. It requires a deep rich soil to grow in.—Q. E. D.

3374.—**Parsley in winter.**—To have a good supply of Parsley in winter, there must be protection in bad weather. One of the best ways of securing a stock is to take up strong roots in August. Cut off most of the old leaves and plant in a very warm position. I have had it do well in a narrow border in front of a forcing house or at the foot of a small wall, or a bed may be planted on a border and be covered with a frame before frost sets in, or sheltered with straw mats. Sometimes a sowing is made in July for winter use. The plants must be thinned out well or the leaves will be small and tender.—E. H.

3375.—**Potato disease.**—A solution of sulphate of copper and lime mixed and applied with a syringe or proper spraying machine before the disease has attacked the plants to any extent will check its farther progress, and ensure a healthy growth and a sound and abundant crop. The best proportions are 22 lb. of the sulphate and 22 lb. of lime to 100 gallons of water; this is sufficient for an acre of ground. The lime must be perfectly fresh and quick, and the sulphate of copper the purest obtainable. The best way is to give one dressing before the disease appears at all on the foliage, say, in the first or second week in July, and a second one about three weeks afterwards. Mix the liquid well, and apply in a fine spray so as to wet every leaf thoroughly.—B. C. R.

3370.—**Onions for show.**—Onions for show should have been sown some time ago. Those who wish to obtain large bulbs frequently sow in gentle heat in February, and when the Onions are 3 inches high harden off, and towards the end of March or beginning of April plant out in row 1 foot apart and 6 inches apart in rows. The ground for Onions must be well prepared by deep digging, and the manure supply must be liberal. If the ground is loose and open pressure must be applied to firm it. I usually tread it over twice. The surface must be dry when this is done. Fowl-manure may be used profitably for Onions at the rate of a couple of bushels to the square rod. This manure is more bene-

ficial on heavy land than light, as it is of a warm nature. When the seeds are sown in the open ground, the same care should be used in the preparation of the land, and the drills drawn 1 foot apart and about half an inch deep. As soon as the Onions appear above ground, dust with soot, and pass the hoe between the drills to loosen the soil and check weeds. When large enough to thin, draw out the smallest and leave the strong plants 6 inches apart. During growth stir the surface occasionally, and use about twice at intervals of several weeks. A light dressing of nitrate of soda, or the nitrate may be mixed with Ichthemic guano at the rate of six pounds to the rod. It is not generally necessary to water Onions in our climate. Still, it is beneficial if there should come a spell of bright, hot weather to give a thorough soaking of liquid-manure ones or twice as weak as loog as hot weather lasts. Water in the evening, and stir the surface the following day.—E. H.

—The large Onions seen at the summer exhibitions are usually produced from autumn-sown seeds. Those exhibited in Lancashire at the autumn exhibitions are produced from spring-sown seed. The Red Onions are grown of the largest size. A single Onion has been grown to weigh 34 ounces; the white variety to 24 ounces. The seed is sown in January in small flower-pots, a single Onion only being allowed in one of the small pots. The plants are grown on in frames and afterwards carefully planted on richly-manned ground, which is also well trenched to a considerable depth. Decayed pig and cow-manure suite them well; manure from fowl-houses is excellent for Onions, but it is very rich in quality, and should not be put on thickly.—J. D. E.

3373.—**Sweet and savoury Herbs.**—The most useful sweet Herbs are Knotted Marjoram, Basil, Summer Savory, Chervil, Balm, Borage, Pepper, Mint, Pennyroyal, Winter Savory, and Tarragon. Pot or savoury Herbs most in use are Thyme in several varieties, Sage, Common or Spear Mint, Fennel (sometimes used as a sweet Herb), and Parsley, though Parsley is generally grown by itself in some position where it can be easy of access in all weathers. Basil, Knotted Marjoram, and Summer Savory are generally treated as annuals, the seeds being commonly sown in heat in spring, and when the weather has settled down the young plants are pricked out in a warm border.—E. H.

Potatoes for heavy land.—"E. H." says on page 16 that "Myatt's Prolific and Impertator are two of the best Potatoes for strong, heavy land." My experience, at any rate, of the latter is just the reverse. Myatt's I have never grown to any extent, but of some score of the leading varieties Impertator gave the worst results of any, the land being a very stiff clay loam on a subsoil of pure clay, but well worked to the depths of nearly a foot. Even with good culture Impertator produced about three tubers to a root only, two of which were diseased. I have given it up altogether. The much-vaunted Bruce also turned out very badly. Magnum Bonum, growing alongside it, producing fully three times the crop, and sounder and of better quality also. The best Potato I have ever grown on this soil is Reading Giant, which turned out at the rate of eighteen tons per acre, affording fine large tubers almost perfectly free from disease, and of excellent quality when cooked. Satisfaction (Sutton's) also does remarkably well here, a large proportion of the tubers running 1 lb. to 1 1/2 lb. each, perfect in form, of delicious quality, and capital keepers. Beauty of Hebron crops well, and the new white variety even better. Duke of Albany yields abundantly, but keeps badly, and is of such inferior quality that I do not now grow it. My best early kind is Sharpe's Victor. All the Ashleas get so badly diseased as to be almost useless.—B. C. R.

TREES AND SHRUBS.

3369.—**Araucaria imbricata.**—It is too late in the season now for you to have much success in raising this grand Chilean Pine from seed in a former garden. I saved, from six or seventeen bushels of seed, annually, and raised many thousands of seedlings.

After several trials, both of growing them in boxes with slight heat and in cool pits, together with sowing in autumn and spring, I decided there was a great advantage in sowing the seed as soon as possible after it was matured. Years ago, when imported seed only was to be had, and the transport took much longer than it does now, one often got only a small percentage to grow. As soon as the cones burst and seeds drop, they will commence to germinate at once if placed in sandy loam. I found a cool pit much the best structure. Use a deep soil of an open nature, and press the seeds down deep enough to cover the wing. Of course you must place them point downwards. Mice are the only enemies you need fear. Do not keep them close except during frosty weather, when a mat thrown over the frame is all that they need. Many Araucarias bear cones, but unless the two sexes are adjacent, they do not get fertilised. A good seed weighs as much as a large Acorn, and even in sound cones there are a great number of thin, wafer-like seeds that are of no use whatever. The cones mature during the second autumn after impregnation. On no account use heat, as you then make the seedlings tender and gain hardly any time. Likes most of the Pines, this Araucaria roots very deeply in the seedling stage.—P. U.

—Sow the seeds now in sandy peat, leaf-mould, and loam, in pans or boxes, and place in cold frames. Cover about one-eighth of an inch. Keep equally moist and shade from hot sunbines till seeds germinate. When young plants appear ventilate a little at first, and increase the ventilation gradually.—E. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 27, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and manure vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

3425.—**Growing Balsam.**—Will someone please to give me some information about the growing of Balsam?—EXETER.

3424.—**Planting Clematises.**—I have just planted three Clematises, and at the time of planting watered them. Is this right?—A. M.

3427.—**Rabbit-manure.**—Will someone be so good as to let me know if Rabbit-manure is a good thing for flowers?—CORRYBRIDGE.

3428.—"Anapargus" Ferns.—I want to propagate some "Anapargus" Ferns. How should I proceed? What heat do they require?—A. READER.

3429.—**Treatment of Ferns.**—Should Adiantum and Pteris Ferns be put, when at rest, into a lower temperature than they are grown in?—A. READER.

3430.—**Annals for show.**—When should annuals like *Conium*, *Aligostea*, *Cypripis*, &c., be sown in the open to be ready for a flower show on August 10th?—A. Y.

3431.—**Keeping rats out of a garden.**—Will anyone kindly advise me as to how would be the best way of keeping rats out of a garden? Is there any other means except poison?—E. T.

3432.—**Peach tree losing its flowers.**—I have a Peach tree, *Lata Admirable*, that is dropping its flowers, which are fully expanded. Would anyone kindly tell me the cause of it?—J. E., *Fortyshire*.

3433.—**Grub in Apple-blossom.**—Would someone kindly tell me of a good remedy for stopping flies from blowing Apple and other kinds of fruit blossom so as to cause the grub in them?—ORSHAM.

3434.—**Early Chrysanthemums.**—I shall feel obliged if anyone will give me the names of twelve Japanese Chrysanthemums, which will flower out-of-doors not later than the end of September?—B. S. T.

3435.—**Constructing a Tomato-house.**—I am just constructing a Tomato-house. Would anyone kindly tell me how high the beds should be in the inside, and if the hot-water pipes should run below the beds or outside the beds? I will have a walk through the centre of the house. Should the pipes run round the walk, and how high should they be from the ground? Full particulars will much oblige.—JAMES MONTGOMERY.

3435.—Garrya elliptica.—I want to have a Garrya elliptica to train on a south wall. When would be the best time to plant, and when might I expect some catkins on it? I should buy an established tree from a nurseryman.—E. H. S.

3437.—Height of Cupressus Lawsoniana Intea.—What is the average height of the largest of these trees? I have one 12 feet 7 inches. If anyone who has larger ones would give their height it may be of interest to others besides.—H. S. Salop.

3438.—Nerine sarniensis.—I have two roots of Nerine sarniensis which have never flowered, though I have had them five or six years. The leaves come up well, and they are rooted in good soil. Should they be reported each year?—E. H. S.

3439.—Clematis (Constance Elliott).—I have a Passion-flower Constance Elliott; it made about 9 feet long and bore flowers at every point last year. Should I cut it back or let it remain as it is—it is beginning to start again into growth?—O. M. S. 187.

3440.—Weeds on a gravel-path.—I shall feel obliged if someone will kindly tell me what is the best thing to use to kill weeds on a gravel path close to a box edging? Is carbolic acid a good thing, or would it injure the Box? I do not want anything injurious to animals.—C. S.

3441.—Tropolium therosum, &c.—I am anxious to know if Tropolium therosum and Tropolium speciosum are one and the same, as I am under the impression that they are? Are they propagated from division of the roots or seed? If the latter, will they flower the first year?—E. H. S.

3442.—Ferns, &c., in a greenhouse.—Will someone kindly tell me why the young fronds of my Maldeohair Ferns turn brown? My greenhouse is on the north side of the house, is heated with hot-water pipes and kept about 50 degs. I should also be glad to know what flowers will bloom best in it?—M. C.

3443.—Fruit trees on Oak fencing.—Will someone kindly give his experiences as to the kinds of Apples, Pears, or Plums that do best when trained on such fences, aspect east and west? Although nominally close fences there is considerable draught between some of the palings which I fear may interfere with the setting of the fruit.—B. W. L. K. 1.

3444.—Chrysanthemum cuttings.—Would "E. M." or someone kindly inform me of the cause why so many of my Chrysanthemum cuttings have started the crown bad? Should the bad only be removed leaving the other three shoots to grow on, or pinch back the plant to a lower joint? Will it be the same if the cuttings are in bloom? I cannot afford to throw out all the offenders as of some sorts every cutting (4) has played this prank. Cuttings were struck in December and January in the usual way. Route d'Or, Foreythe, Stanzel White, and Deleane are the principal delinquents.—E. H. P.

3445.—Fear Bishop's Thimble.—Will anyone kindly inform me why my Bishop's Thimble rose on the tree before they are ripe? I have several trees of them in my garden; the trees look very healthy, and there is, as a rule, an abundance of blossom on them; but invariably when the fruit has nearly reached its full size, and, of course, some time before they are ripe, the majority of them commence to rot at the eyes, and soon those which do not rot on the tree commence to rot at the eyes after being picked a short time, and before they are fit to eat. What should I do to remedy this?—K. Y. Z.

3446.—Height of Chrysanthemums.—Will "E. M." kindly tell me about what height the following Chrysanthemum plants grow to, measuring from the bottom of the pot: Mons. Barraud, Bouras d'Or, Bouquet Felix, W. Robinson, roseum superbum, Maiden's Blush, Val d'Andorre, Peter the Great? I intend stopping these twice to get a nice lot of blooms. Also Miss. Marthe, Golden Mlle. Marthe, Elice Dordon, Black Douglas, Automne, Marie Stuart, and Mms. Montale. To be grown six blooms on a plant. All of the above plants were rooted by the first week in March. Also what is best to use for worms in the pots? I was very careful last year about trying to keep them out, and kept them standing on boards; but when I turned the plants out there were fine fat ones, that I supposed had been gorging my stimulants that I intended for my plants. I heard once something about lime-water being used for it, but I do not know what strength, or how often it should be applied. I shall be much obliged for advice.—W. D.

3447.—Failure of hot-bed to heat.—Will someone kindly enlighten me as to the reason of my hot-bed not heating? I have had a new brick pit built, size about 7 feet by 6 feet, and 4 feet deep, which I have had filled with horse, pig, and cow-manure (principally the former), the whole being well trodden down. This I have done three weeks ago, and as there was absolutely no heat arising from it at the end of two weeks (nor had there been at any time during that period), I decided to try a plan recommended by one of your readers—viz., to take out nearly half of the manure and out a lot of Grass and put in the middle, replacing the manure on the top. Strange to say that, although the manure when placed in a heap on the ground showed unmistakable signs of heating (in fact, it got quite hot in the course of twelve hours), after the bed had been remade, with the Grass in the middle, it has shown no signs of heating whatever. Will anyone tell me where the fault is? Here I trodden it too much, or put in the wrong kinds of manure, or what?—X. Y. Z.

3448.—Roses all the year round.—I am anxious to be able to out a few Roses all the year round. I have plenty of garden spaces protected from north and east to grow outdoors. Roses outdoors should, I fancy, take me on to October. In a lean-to greenhouse facing south (30 feet by 12 feet) I have a Gloire de Dijon and Marechal Niel, which give me flowers at end of February. It is fitted with heating apparatus, which I only use in very cold weather. Then I have a small house (16 feet by 7 feet) in which I could force pot-Roses to bloom from November to February inclusive. Will "J. C. C." or "P. U." tell me how to treat pot-Roses for my purpose? Should I let them flower now? I suppose that I may put them out of doors in July. When should I prune them, and what should I take them into, first, the cool, and second, the hot house? I suppose that I can keep some in the cool house and transfer to the hot when some of those in the

hot-house have finished flowering. I have bought plants of most varieties recommended in GARDENING lately, but will get any other kinds if I can accomplish my desire to be able to cut some, say every Sunday in the year?—A. M. K.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3149.—Indian Filbert (J. Muir).—Yes, this is the name the seeds are known by, and they are the seeds of a Leguminosae plant called Eotada scandens, which climbs to a great height, and the pods sometimes reach 7 feet and more to length. I do not know if it is in cultivation.—J. J.

3150.—Odontoglossum Malus.—J. Ebdon sends a flower which is evidently this plant, but I do not consider it at all a pretty flower; at any rate, I have seen much handsomer forms with a better lip. The plant named Malus usually produces a branched spike, or it does, say, when the plant becomes sufficiently strong, and so, perhaps, may yours when it becomes robust.—M. B.

3451.—Monkey Bread.—J. Muir asks what is that it is the fruit of an African tree called Asconia digitata, which grows nearly as thick as it is high. It is considered to be the oldest tree upon the earth; some existing specimens are said to be five thousand years old. The fruit is oblong, nearly a foot long. Another species of this family is found in North Australia, but its fruits are very much smaller. I do not know if they are in cultivation.—J. J.

3452.—Easter Palm.—J. Muir says I should like to know from what tree the Palm usually worn at Easter is obtained? The flowers that are worn so much at Easter time and vulgarly called Palm are the catkins of the common Goat Willow (Salix caprea). I saw it last week about the neighbourhood of Dorking, Leatherhead, and the neighbourhood, very gay and beautiful. There are many species of Willows which are natives of those islands also, but they are a difficult genus to make out. The present one is a very common plant.—J. J.

3453.—A large Palm.—J. P. M. says she has a large Palm in her greenhouse which must be removed. She sends a leaf and drawing to enable me to name it, by which I see that it is no Palm at all, but a very fine specimen of Dacrydium australe, and I have little doubt but it would live outdoors in a well sheltered position in the Co. Waterford; but even if you do not like to risk this plan you may cut the stem partially through, taking out a good cut as near to the ground as possible, and so the plant will die, a considerable mass of Sphagnum Moss, keeping the stem always sopping wet. Do not allow it to become dry for a single minute and you will be rewarded by its sending out roots late in the year. When this occurs cut it a little more at different times till at last you take the head quite off, when it may be carefully potted and kept very moist and shaded for a time, but it will soon root and do well, and you will have a handsome plant minus the bare stem.—J. J.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—Jas.—We cannot name from such scraps.—J. Atkins.—1, Odontoglossum Ceraeotesi decorum; 2, Lycaste macrophylla; 3, Mexilistia grandiflora; 4, J. T. M.—1, Asola Dromaeoides; 2, Leucopogon lanceolatus; 3, is one of the hybrid Rhododendrons; it looks like Duchess of Edinburgh.—C. Hodgson.—1, Davallia dissecta; 2, Lactaria glabella; 3, Adiantum formosum; 4, Selaginella larocensis; 5, Selaginella formosa; 6, Cyrtium talostem.—J. K. Evans.—1, Theophrasta imperialis; 2, the Loquet (Eriobotrya japonica); 3, Miroplepia hirta orientalis; 4, Antherium variegatum; 5, Lygodium japonicum; 6, Nephrolepis Duff.—Nemo.—1, Vealei japonicum; 2, Dendrobium coherentum.—J. Broom.—1, Dendrobium nobile Cooksonii; 2, Avides Fieldingii; 3, Dendrobium Hittorferum; 4, Odontoglossum malus; 5, Oeodidium divaricatum; 6, Trichopilia corallia.—G. D. B.—1, Davallia solida; 2, Dorella Mooreana; 3, Adiantum hirsutum; 4, Barclaya (the ordinary form of Cattleya Triana).—J. Johnston.—1, Sophronitis cœnea; 2, Lycaste aromatica; 3, Dendrobium Pterard.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Mrs. V. S. Knox.—Apply to Messrs. J. Backhouse & Son, York.—Enquirer, St. Ives.—Wireworm is the cause of the mischief. Bury some pieces of Potato in the ground and mark the spots with stakes, and take these pieces of Potato up occasionally and destroy the wireworms that rot will find there congregated.—A. Hunter.—Vines and Vine Culture, by A. F. Barron, price 6s. 3d., post free from this office.—Willesden.—Keep the greenhouse at a temperature of about 50 degs. to 55 degs. by night, and about 60 degs. in the day-time, and the Vines, &c., should do well.

Catalogues received.—Pansies, &c. W. Paul & Co., Bridge of Wair, N.B.—Seeds, &c. Messrs. Vilmorin-Andrieux & Co., 4, Quai-de-la-Mégisserie, Paris.—Hardy Trees and Plants. Mr. F. W. Kelsey, 145, Broadway, New York.—Agricultural Seeds. Messrs. E. P. Dixon & Sons, 16, Wellington-street, Hull.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of new and rare flowers and good fruits, and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

POULTRY & RABBITS.

QUERIES.

3454.—Pallet containing to lay miniature eggs.—Early this month I bought some pullets. One of them (a full-sized healthy bird) began to lay lately, and lay almost every day, the size of each egg being a little larger than a marble and without any yolk. Weight, three to the ounce. I have now over a dozen all exactly similar. Please say is this an unusual case, if there is any chance of the size increasing, or if I can treat her in any way to make her lay the ordinary-size eggs?—P. M. 1.

3455.—Poultry keeping.—Would someone kindly give me a little information on poultry-keeping. My object in buying what I have was to always have a supply of eggs. I have a large garden and a good pen, with three cocks and ten hens. I intend reducing the cocks to two. Should I separate them out? What should I feed the hens on for laying, and the quantity and number of times to feed per day? The chickens I bought them from is a friend, and he says they are very big—Minoras, but there are some white ones among them. Are there any white Minoras? I have had them ten days, and only had two eggs. I don't know if I fed them enough or not. There is always a great rush whenever any food is taken them. I give them plenty of water, but they make it dirty. Must the vessels be spotlessly clean when fresh water is given?—Zoox.

REPLIES.

3366.—Hens not eating.—"B. C.'s" hens were suffering from a severe form of diphtheritic crop or canker, and I consider that he noted wisely in killing the birds at once. By adopting this course he has probably prevented the disease spreading, and may thus have saved the remainder of his flock. The temporary loss of eggs—though not easily explained if the other fowls have not taken the disease—is a matter of trifling moment if the stock can be spared. I cannot this week go into particulars as regards treatment, nor is it necessary, under the circumstances. I may, however, say that whenever a disease of this kind breaks out it is almost the best plan to isolate the fowls at once, and thus check its progress. What has caused the present outbreak is not easy to say, if the sanitary arrangements are good and "B. C." has purchased no new stock. I would advise the querist to examine the fowl-houses very carefully and remedy any defect which may exist. I have recently had a visitation of this disease, a newly-purchased cockerel falling a victim soon after his arrival, and a hen soon followed suit. This, I am of opinion, was introduced by the cockerel, although he came from a large breeder-dealer, and was bought at a high price. A second hen I killed, but was more fortunate with another.—DOULTON.

3368.—Feeding Rabbits.—"Burton" is using foods which are far too heating for young Rabbits, and to this I attribute his failure. Instead of Bean or Barley-meals I should use crushed Oats, and for a change give a little Carrot or Swede Turnip. If any green stuff can be got, so much the better. In most gardens there are a few Cabbage-leaves to be met with. The Rabbits, too, are too early, and I am inclined to think are too delicately bred. At any rate, there must be something unusual amlen when so many die together and the survivors cannot be induced to eat.—DOULTON.

3367.—Ducks not laying.—I can say nothing as to the absence of eggs beyond suggesting that the birds may be too fat or belong to a bad laying strain. Handling the Ducks would convince the querist on the former point, and enquiry amongst those who know how the birds are bred should satisfy one as to whether the number of eggs produced so far is below the average. A small run would not be likely to choke laying altogether; indeed, last year I knew a cottager with a small run whose birds were very prolific. Nor would the company of hens be a drawback, provided the birds were well supplied with food.—DOULTON.

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free, 6d.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 6d.

"Wild and Garden Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species with illustrations of their arrangement, culture, &c. With an Appendix, 1s.; post free, 1s. 3d.

—C. M. 1. 18, Southampton-street, Strand, W.C.

HOUSE & WINDOW GARDENING.

VAN THOL TULIPS FOR ROOM DECORATION.

Few plants are so refreshingly bright in early spring as Van Thol Tulips, and the enormous quantities sold in our flower shops at about this time of year testify to their great popularity. They are so easily cultivated that most of us might supply ourselves with plenty of these lovely blossoms with a very little attention and care. The pots containing perhaps five Tulips, all in bud, just bursting into bloom, which we see in florists' windows, are apt to excite the envy of the amateur, whose groups are by no means so perfect, perhaps marred by a failure amongst the bulbs, or spoiled by the fact that one flower is over before the rest open their blossoms. But the secret of ensuring a perfect potful of Tulips is a very simple one. The bulbs, obtained as early as possible in autumn, are placed thickly—i.e., at intervals of three inches each way, in a shallow wooden box about eight inches in depth, well drained, and filled with very light sandy soil, containing a little leaf-mould but no stable-manure. Here they remain in a cool greenhouse (for they will not bear much foreign in their early stages) until they show well above the soil, when they may be introduced to a temperature of from 50 degs. to 70 degs., this last allowing for sunshine; but green-fly must now be looked for, and sponged off if it appears. A slight bottom-heat, such as may easily be had by placing the box on the heated pipes of a conservatory, will bring them on rapidly, and as soon as the buds can be well seen the bulbs may be selected, and potted up without deger, placing those together which are equally advanced, either three, five, or seven, closely in suitable-sized pots, which need only just hold the plants with as much of the light soil in which they grow as can be made to adhere to the roots. Plentiful watering, and a top-dressing of fresh green Moss will make them ready for the drawing-room. I. L. R.

CYCLAMENS FOR WINDOW CULTURE.

THESE lovely and fragrant flowers are of very easy cultivation, and the best of room plants, for they continue in bloom for many weeks at the time of the year when flowers are most difficult to procure, only needing a warm sitting room window and the absence of gas to enable them to do well. They can now be procured, well set with buds, and will require little beyond a regular supply of tepid water, an occasional cleansing of their leaves, either with a bit of soft, old sponge, and clean, soft water, or by setting the plant in a bath, and giving it a douche from a rosed watering-pot. Cyclamen corms, when once established, will last for years with proper care. Unfortunately most furnishing plants, when they cease flowering, receive no attention, and are allowed to die for want of water, because the beauty is over (or

the present, many people fancying that they should be dried off, which, in fact, does this work most effectually, as the unfortunate plant does not survive the process. The fact is, however, with regard to almost all bulbs and corms (though not so often in the case of tubers, such as Begonias, &c.), that the time after blossoming is the most important period of their existence, for it is then that the embryo blooms for the next season are formed, and this cannot be done without the gradual dying away of the foliage, which acts to the corm something in the way that our lungs do to us, and therefore cannot be suddenly dispensed with. Cyclamen after flowering should still be regularly watered, though not so often supplied as when in bloom, and at the end of May they can be sunk, pot and all, in a half shady border for the summer, a mulch of good leaf-mould and old hot-bed stuff being spread round the corms (which should not, however, ever be entirely covered) to nourish the plants. Here they may stay until September, when the pots can be taken up, the plants taken out and repotted, shaking off all the old soil, and potting them firmly in a good compost (which can be bought ready mixed), of leaf-mould, loam, equal parts, with a little very old manure, and a dash of soot, with enough sand to make the compost light. Drain the pots thoroughly, and set the plants in a sunny window near the glass (if a greenhouse be not available) to start, turning them round daily, so that each side is evenly exposed to the rays of the sun. They will often be covered with buds when taken out of the ground, and should soon begin to open then, if kept in a warm room. It is, however, well to remove them at night, in frosty weather, from the vicinity of the window, and to avoid freezing draughts for them, during the time the room is brushed in the morning, by taking them into a bedroom in cold weather. I. L. R.

3408.—Plants for a flower-box.—There is nothing prettier as a trailer for a window-box than a good variety of Ivy-leaved Pelargonium—Madame Crousse or Madame Thibaut being two of the best. But the plants, to do well, must be carefully prepared before they are put out at the end of May by being repotted now and the ends of the sprays pinched off, so that lateral growth is encouraged. When they have been shifted a week or two, weak doses of soot-water should be given, keeping the plants in a warm greenhouse with plenty of sunshine (or a sunny window will do for them), and these doses of liquid-manure, given at first once a week, can be doubled as the plant becomes strong, so that in this way they should be full of bud by the time they are put out, and will make a bright show of colour all the summer. Plants of Money-wort—which grows a long, straight fringe of golden blossom—alternated with Blue Lobelia, also look well in a window-box, or Enchlasia which have been potted and sharply cut back in spring, and allowed to make long sprays of growth. These can be tied up to a neat stick or allowed to hang over the edge of the box as preferred, and will flower profusely. Tuberosa Begonias, however, of a drooping but well habit (such as are sold for growing in

baskets) are the most striking objects in a window-box, if well grown. They must be gradually hardened to the open air, and supplied with plenty of water, and a mulch of Moss or Cocoa-nut fibre over the surface of the soil in which they grow, for their well doing depends largely upon the network of roots which they form just below the soil, and these dry up in hot sunshine. As "J. Goudge" mentions Caery Creeper, it is not, however, quite clear that he does not mean climber, not trailers, as needed for his box. If so, he might try Lophospermum scaedens, a very pretty pale-pink creeper with handsome foliage; or Eceemocarpus scaber, with bunches of yellow and scarlet flowers. These should be bought as strong plants of last year to do well this summer. Seedlings now put in would be too late to do much. "J. Goudge" should select plants of any of these things which will suit the tints of the Clematis, which may be purple, lavender, or white, the variety not being mentioned. Rich light soil, plenty of water, and soot-water given once or twice a week when the box is full of roots will be necessary. Flowers surrounded by air and in the full sunshine in a window-box need much more moisture than if kept in a greenhouse, and a regular supply, at least once every day, should be given with a douche from a rosed watering-pot on warm evenings.—L. R.

Ivy-leaved Pelargoniums would be suitable for the purpose, and you will find they will remain in good condition until the autumn with a little care. The position is an important one, and you want something that will present a gay effect. Creeping Jenny, the Tropaeolum, and Canary Creeper—the latter, especially, are very pleasing—but as you do not seem to care for these, select the Ivy-leaved Pelargonium. Put in good strong plants of a well-chosen variety, as the clear rose-pink Mons. Crousse, which is effective and free.—C. T.

Few plants could be more suitable than Ivy-leaved Pelargonium. A combination of Victoria, Masterpiece, Innocence, and Campanula fragilis would have a very pretty effect.—A. O. BIRGER.

3385.—Treatment of Spiraea japonica.—This plant (presumably bought for room decoration) must not be allowed to want for water at any time of its existence, although it does not, of course, need such plentiful supplies after its flowers fade as when it is growing rapidly. As soon as the blossoms are over they should be picked off (leaving the foliage intact), and the plant can then be put out of its pot into any good open border to rest for the summer. The root may be divided into two or three parts (according to size), and each of these will make a good plant for next season. The foliage will gradually ripen off, and the crowns (or embryo plant for the following season) become strong if kept watered in hot weather. They can be potted up in November or left till March in the open soil, for the plant is perfectly hardy. If wanted early they should be potted up early, and gradually brought in in slight warmth (a sunny window will do), giving them constant supplies of water when growth begins, and syringing them often (or watering with a rose) to keep off green-fly. Plants grown in a window need to be turned

round often, or will be lopsided; but with a little attention and care *Spiraea japonica* is an excellent window plant, and most decorative for a table or drawing-room. Should the present plant have been starved for want of water after flowering it will do but little next season, and should be allowed to stay in the open border undisturbed for an extra season, when the plants will have grown very strong. It is as well, however, in this case to take them up in the autumn and divide the roots, putting them at once again into the border, or they will get too large for anything but a large-sized pot, and it injures them considerably to divide them when they are potted up. Rich soil and good drainage is essential for potting *Spiraea*.—R.

GARDEN WORK.

Conservatory.

Cyclamens sown in autumn will now be large enough to transfer to 5-inch pots; but spring-sown plants will only be in condition for pricking off. Some of some kind generally be obtained everywhere; but really good loam suitable for general plant-growing is not so common. Good loam can easily be distinguished from that of inferior quality by its touch. It soft and silky to the feel it may be used freely for almost everything except hard-wooded plants, and when this loam can be had it may be used freely in potting *Cyclamens*, *Double Primulas*, *Ferns* and other plants for which peat is frequently used. *Cyclamens* ripening seed must be looked after, as the seed soon dries. Chinese *Primulas*, also, and *Chlorocaris* will require watching. Early *Fuchsias* will soon be showing flower. My earliest batch of autumn-struck plants, and which have been kept moving all winter, are showing blossom-buds. Of course, the plants are not so large as they might have been if potted into larger pots. One of the peculiarities of *Fuchsia* culture is this: Almost the moment the roots work through the soil given at the last shift, and begin to feel the sides of the pot, blossom-buds begin to form, and beyond the elongation of the flowering-shoots, there will not be any more growth; therefore, if large plants are wanted shift on in rapid succession before the flower-buds form. *Hibiscus* are now coming in, and may have weak liquid-manure. Large specimens are very desirable for the conservatory; but small plants now last August and now carrying one large brass of blossoms in a 5-inch pot are very useful for the drawing-room table or stand. A small quantity of iron in the soil will give a blue tint to the blossoms. *Chrysanthemum* will draw too much if kept now where the heat is used. Move to cold frame, but cover up nights, as frost sharp enough to injure the growth may come yet. Shift on to larger pots before the plants get pot-bound, and see that no plants suffer for want of water. The watering now is getting a rather heavy business; but the sunshine has been quite phenomenal for the season, and if a little shade is used over plants in blossom no great harm will be done. It is not doing the *Primulas* and *Chlorocaris* for early blooming. It is always advisable to make at least two sowings of these things. It is rather a bother now, so many other plants require extra space under glass, to be compelled to keep the things going out of blossom under cover; but it must be done unless things are to be sacrificed. Fertilizer shifts if properly looked after need not be useless after the first year.

Stove.

Young winter-blooming stuff coming on must never be checked for want of pot room, nor yet be permitted to run into weakly growth for want of a timely pinch with the finger and thumb. Of course, where there is a warm pit or an intermediate house, much of this young stuff will be moved on from the stove. Cuttings of *Gardenia*, *Euphorbia*, and *Polka* should be put in now. It often happens that the cuttings of *Polka* can be had later in the season than now or earlier. I have noticed to say against late-struck *Polka*, as we are always glad to get them late as well as early. They will strike well now in sandy peat or leaf-mould, with plenty of sand, in a brisk bottom-heat. Cuttings of *Croton* and all other foliage plants usually propagated by cutting will do well now. *Caladium*, *Maranthus*, and other foliage plants are making rapid progress, and may be increased if desirable by division of the roots. *Caladium* will do in stronger soil than the other plants. I have had all the strong-growing *Caladium* growing splendidly in turfy loam and drainage being properly seen to. The small delicate varieties, such as *agryria*, will do better in sandy-peat without any manure, though a dash of leaf-mould will be an advantage. Pot off early-struck *Bourvardia*, and put in more cuttings. *Repot Eucharis Lilies* should it be desirable to break up any of the old clumps. This is the best season for repotting, as they may either be potted singly, or three or more bulbs can be placed in each pot. The drainage must be perfect, and the soil best turfy loam and very old manure. I am always rather reluctant to break up old clumps of roots, as it takes so long to work up large pots full again so as to produce abundance of flowers.

Unheated Greenhouse.

The time is at hand now when a boiler and pipes so far as regards greenhouse work will not be required; hence the unheated greenhouse is quite as useful as where heat is employed. The double *Tiger Lily* is a very desirable pot-plant. From three to six bulbs in a large pot will make a fine specimen, and this class is hardier and less affected by green fly than the *Bermuda Lily*. Place in the centre of the arched flower-stems are a terrible nuisance, and rather difficult to dislodge. Tobacco-powder or snuff is perhaps the best remedy. Variegated Grass of large size, such as the *Arundo Donax variegata*, and others, are always effective. Anything that requires

a shift may have it now, and, of course, *Chrysanthemums* must be kept moving. *Misk* and other *Mimulus* will be moving now. Some of the hybrid *Mimulus* are very pretty, and will flourish in the cool-house.

Forcing-houses.

There are plenty of flowers which bloom naturally at this season, so flower-fearing is not in many cases so urgent; but at this time a warm-house can always be utilised probably for helping on anything which requires heat to make growth, or to bring on young stock so as to relieve the pressure of the stove. There is besides plenty of propagating to be done yet, and in addition this house can be made available for Cucumbers, Strawberries, or Figs in pots.

Cold Frames.

These are in great demand now for hardening off bedding-plants and to relieve the fruit-houses. Temporary places may be roughly constructed with boards, to be covered at nights with mats or siled calico, for pricking out Stocks, Asters, and things of like character. Celery-plants will far a little time yet require a little shelter after pricking off.

Window Gardening.

Give liquid-manure to *Pelargoniums*. Keep *Cinerarias* and *Calceolarias* in the shade. *Tuberous Begonias* are now starting, and should be repotted, using turfy loam, leaf-mould, and sand, with plenty of drainage in the pots. *Scarborough Lilies* where necessary should be repotted. Keep the bulbs bare out of the soil. They do not thrive so well when completely buried. Pinch the long shoots of *Fuchsias* to make the plants compact in habit, and take all plants neatly. Spooze foliage where required. Divide *Aspidistras*, and *repot Palms, Ferns, and Indian-rubber-plants* if required. Do not overwater newly-potted plants; it will make them unhealthy.

Outdoor Garden.

Recently-planted Roses and shrubs must be mulched and watered. For some time now the weather has been delightful, but rather trying to evergreens recently planted. Keep the foliage dry by the use of the syringe or garden sprayer. Hundreds of trees and shrubs are annually lost for the want of attention in the matter of mulch and water. A little mulch of old manure or leaf-mould will be beneficial to *Carnations, Fuchsias, and Pansies*. I am using the old manure which has been taken out of the Cucurbit-houses. Old Mushroom-beds well broken up and mixed with a little loam will be valuable for the same purpose. The seeds of hardy annuals will soon germinate now if the surface soil is very dry and it is watered just previously to sowing the seeds and the latter covered with a little fine-sifted leaf-mould, the seeds will grow speedily. When the seed is low in the ground the plants are often weakly when they struggle through. Ivy on building if not yet trimmed in should be done at once. Ivy will not make walls damp if trimmed in close annually. I usually take the shears and cut everything off close to the wall, or, at least, as nearly as one can use the shears without injuring the branches which cling close to the wall. Grass-seeds for the improving of weak or bare lawns may be sown now. New Lawns also may be seeded down, or turf laid in place, if preferred. It is not a good plan to have a lawn laid at a reasonable cost, if it should never be used. It is useless expending to get a good turf in a reasonable time, if you are sowing seeds on very poor land without manure. Evergreen shrubs of all kinds, except *conifers*, may now be pruned. Cuttings of evergreens, both under glass and on shady borders outside, must be kept moist. A little mulch between the rows will do good.

Fruit Garden.

The bright sunshine has been a great help to the fruit force. Vines, Peaches, Figs, Melons, and Strawberries under glass have come on considerably, but the extra warmth and brightness has necessitated extra attention, especially in the matter of damping-down. In the growing of Vines after they have broken, but moisture is liberally supplied by damping floors and borders. In bright weather this damping is done in the middle of the day as well as morning and evening. In a very hot day a few pots of water thrown on the paths of Peach-houses or Vineries is a great support to the foliage, and often prevents scorching or scorching. Ventilation must be closely watched now, especially in the morning. Begin by opening the top lights, and as soon as the temperature begins to rise from the effects of the sunshine, and increase the size of the opening gradually as the temperature rises. There has been a good deal of tying required both among Grapes and Peaches. Strawberry canners also have had a trying time, but there are compensations—the work of two or three weeks has been done in one. This may not in all cases be an advantage, still in most cases rapid growth is desirable. See that inside borders are in a moist condition; both Peaches and Grapes will take a good deal of nourishment where the drainage is free and the roots live. Strawberries outside will soon require mulching with long manure. If the weather continues dry the mulch will conserve the moisture in the land, and Strawberries are thirsty plants. Remove covers from wall trees as often as possible to let in air and sunshine, if the covers are close and heavy. When fishing-nets only are used they may remain on till removed altogether. There is a wonderful prospect for Apples and Peaches.

Vegetable Garden.

Forced vegetables have come on rapidly under the influence of the bright sunshine, and have made a corresponding demand upon the time of the cultivator. It is glorious to be able to open ventilators to their full width. Potatoes, Carrots, French Beans, and other crops coming on in frames have benefited immensely by the free ventilation and the weak liquid-manure which we have been able to give them. Cucumbers in houses worked on the non-ventilation system have grown rapidly with the main food, and with a little shade for a few hours during the hottest part of the day. When Cucumbers are grown on a very large scale the shading consists for the most part of thin whitewash, mixed with a little size, syringed over the glass. This shades sufficiently without darkening over much. I find Cucumbers do well under such conditions. Where but little air is given frequent dressings of rich turfy compost are very

beneficial as the roots are constantly working through to the surface. The last fortnight has been a splendid time for Tomatoes, blossoms not needed in the basement atmosphere, and it must be from sheer bad management if there is any disease. It is rather too soon yet to plant unheated houses, but the borders should be got in condition to secure the plants as soon as it is quite safe to trust them in a house without fire-heat. This is a busy time in the kitchen garden. Successional crops of Peas, Beans, Spinach, Lettuce, Turnips, etc., should be sown. Prick off Celery, Cauliflowers, Brussels Sprouts, Lettuce, Leeks, and Onions raised under glass; sow main crops of Carrots, Solei, and Scorzonera. Main crops of Peas may now be sown. The Turnip-rooted kind is the earliest, and a row at two feet should be set in early. Splendid weather for planting Potatoes. Do not forget in a few plenty of room. E. HEDDY.

Work in the Town Garden.

Away from the smoke some amount of shading has been necessary during the middle of the day, as for the past fortnight or more the sun has been extremely bright and hot; but in large towns a lot of this kind of work is done for one, the fall of smoke and frequent fog acting as a sort of blind, and largely tempering the sun's rays. In addition to reducing the amount of labour in the garden, it is well to have a lot of labour in watering; but do not carry it too far, for sunshine solidifies the new rapidly expanding tissues, and the more sun a plant can stand without distress the better far it is in every way, as a rule. The more heavily you shade the more shade most plants require. A movable blind is best, and it should not be drawn down until really necessary, and taken off directly the sun begins to go downhill a bit—at this season by about 3 p.m. at the latest. Propagating will still be proceeding, and where a lot of stuff has to be worked up occupies a lot of time. Cuttings of *Fuchsias*, *Penulias*, *Heliotropes*, and, indeed, almost anything will now root in a very few days if inserted in well-drained pots or boxes of sandy soil, and plunged in a gentle hot-bed, or kept warm, close, shaded, and moist in a house or pit, which must be well-ventilated. If potted off singly directly roots have been found, and before these have run so far as to be liable to get broken in the operation, and again kept warm, close, and moist for a time till established, with cutting down the plants as soon as they are good plants for the bedding of June as they get in a month or two earlier. Continue pricking off seedling *Begonias*, *Gloxinas*, and others, for if left too long in the seed-pans they often damp or "fog" off wholesale. For all work of this kind I like to fill the pans nearly half full of drainage, with a layer of rough siltstone over, and then one can water them almost ad lib., with no fear of scouring the soil. I am just now potting off a batch of seedling *Streptocarpus*, which were sown rather late last summer, and have stood the winter in a "stone" pot. They are growing fast, and must be made to take capital and I believe these will prove to be very good town plants, but the chief drawback to their general culture is that the seed is so excessively small that it requires some amount of silt, and a great deal of care, to get it up successfully. Tomatoes ought to be planted out under glass as soon as possible now. It is rather early yet for unheated houses, but if there is just enough heat to exclude frost good strong, well-hardened plants will do right enough now. I like the 5-inch pot size to plant out from heat, either indoors or out. B. C. H.

THE COMING WEEK'S WORK.

Extracts from a garden diary from April 8th to April 15th.

Looked over early Tomatoes and rubbed off side shoots, tying up main stems, etc. Always make the borders with short manure where the bottom trusses have set, and the plants require more food. This mulch is absolutely necessary in the case of borders raised above the natural level. It saves so much time in watering, and the plants do better when the roots are in an equable state of moisture without so much watering. Watering in hot weather is not an unmixing good, and a watering of short manure as a mulch keeps the soil comfortable as a trifling expense. This mulch is beneficial to crops growing on warm early borders, which are generally raised above the natural level considerably. Filled the shelves in an unheated house with Strawberry Sir Charles Napier. This is a splendid variety for late forcing, where plenty of ventilation can be given. Good favoured Strawberries cannot be grown without plenty of ventilation. On hot days I open all the lights the full width, and generally set open the doors as well for a few hours in the middle of the day. The blossoms set so freely when the currents of warm sunny air circulate among the foliage and flowers. Soon after three the houses are closed, and the engine or syringe is used very freely, rain water which has been exposed in a tank in the sunshine being used. This is the time to force the crop. The thermometer may run up about 90 degs. with a saturated atmosphere. The fumes are kept down during the day, but I always contrive to have the pipes comfortably warm when the natural warmth which has been shut up in the house declines. This, I take it, is the secret of successful forcing. Let the sun do the work when it will, but meet the declining temperature with the fire. Thinned Peaches in second house. The house contains a dozen trees, and all have set better than usual this season, necessitating very much thinning. When a heavy crop of fruit has been set I hold it is a mistake to leave the young fruits that are not required on too long. There is one advantage in having Abundance; the fruits left for this crop can be placed on the upper side of the branches, and so be brought immediately under the influence of the sunshine. Put in cuttings of carpet-bedding stuff, especially the bright-leaved *Alternanthera* and *Impatiens*. These are very easily rooted, and are indispensable for producing the effective colonizing of the foliage beds; but carpet-bedding only lingers new in most places in comparison with what was done 20 or 30 years ago. The time moves so rapidly looking back on the past quarter of a century seems but as yesterday in some respects. Sowed more *Miracoste* and Sweet Peas with a large collection of annuals. To do them justice I should say should be well done. Sowing

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equal success.

annuals among strong growing herbaceous plants is a common practice, but not a good one for bringing out all the effectiveness of the annuals. I was forcibly reminded of this last year. Three years ago I planted a new herbaceous garden, and filled in the spaces between the borders with annuals. The latter did splendidly the first year, but they have never done so well in the same beds since the season during the herbaceous plants have occupied the soil with their roots, and the growth above ground shades the annuals too much. Planted Hollyhocks, and prepared sites for Dahlias. Trod the surface of Carnation beds, as the soil must be firm

INDOOR PLANTS.

NEGLECTED GREENHOUSE PLANTS.

PIMELEA SPECTABILIS.

This fine plant, of which we here give an illustration, was introduced into this country from the Swan River district of Australasia nearly fifty years ago, and has always been a favourite with growers of New Holland plants. The genus belongs to the Daphnoid family (Thymelaeaceae), and contains numerous handsome species, which are alike useful in the conservatory or for exhibition purposes, as they travel well without brising. This plant is a strong, yet compact grower, a profuse bloomer, and of tolerably easy culture. The soil best suited to this plant is a mixture of peat and loam, in the proportions of about three parts of the former to one of the latter; to this should be added sufficient sharp sand to make the whole feel gritty, whilst

house and a range of frames. The other house is heated by a flue which goes round like the letter U in shape. I have no side flues to the boiler. The whole acts very efficiently, too much so sometimes. The fuel is extremely poor, but the large fireplace gets over that difficulty. The only drawback is the amount of clinker formed—great cakes as heavy as I can lift; but, having no firebrick in the furnace the clinker is always free—no sticking fast, very different to the stickfast clinker I had to contend with last winter. I can leave the apparatus ten or twelve hours easily.—Economy.

STREPTOCARPUS.

ALTHOUGH the Streptocarpus have been known in this country for more than thirty years, only a very limited number of cultivators thought them worth attention. It was left to Messrs. Veitch and Son, of Chelsea, to popularise them by introducing a greater variety of colours. In this respect the improvement has been very great, and for the greenhouse we have not had a more valuable introduction for several years, as the plants are not difficult to raise from seed, and one-year-old plants will continue to flower the greater part of the summer. Anyone having the command of a temperature of 60 degs. may sow the seed at once, and if the young plants are carefully tended they will flower towards the end of the summer. It is,

in not likely to make a good room plant, as the surface of the leaves is somewhat woolly in character, and likely to retain any dust flying about.
J. C. C.

BEDDING "GERANIUMS."

THESE very useful plants are frequently lost in great numbers during the winter from excess of moisture at the root and in the atmosphere, and probably a great many more, especially of the tender variegated kinds, are lost from this cause than by the action of frost. The best plan of keeping the stock safe that I have found in to get them well rooted either in small pots or shallow boxes, and from October until February give but very little water at the root, just enough to keep them from flagging. The best place for them is on shelves near the glass, and everything should be kept quite clean. If the pots or boxes are just taken off the shelves and all decayed leaves picked off, and the surface soil slightly stirred it is surprising how the plants are benefited. Fire-heat should not be used to promote growth at this dull period of the year, but more to dry up damp, and for this reason it is best to warm the pipes or flues during the day, when the ventilator can be opened at the same time. Old plants that have been lifted and potted need a good deal of cleaning to keep the shoots from rotting off, and not only the leaves that turn yellow require removal but especially the little leaflets that form at the junction of the leafstalk and stem, for if they are left to decay on the shoots they soon affect the whole shoot. A little extra attention in getting the stock safely into the new year will be well repaid in spring by an abundant stock of plants.

J. G., Hunts.

Pimelea spectabilis. Engraved from a photograph.

thorough drainage is indispensable. After flowering is over the plants should be cut back tolerably hard, in order that they may be well furnished with foliage at the bottom. Potting should be performed just after the stems begin to put forth young shoots; the soil should be made very firm, and water must be carefully supplied until the roots begin to get established in the new material. Just at this time a slightly warmer and moister atmosphere will be beneficial, but when somewhat established the plants may be removed into the greenhouse again. During the earlier growth the shoots should be pinched off once or twice to keep the plants bushy, but this stopping of the growth should be discontinued after the month of July, or they will not have sufficient time to ripen up and form flower-buds for the ensuing spring. The flowers are produced in large woolly white heads upon the points of all the shoots, and they last in full perfection for a considerable time. The variety rosea is rather a stronger grower than the typical plant, and the flowers are all tipped with rosy-pink, thus rendering it very distinct and a fit companion for the species.

G.

however, in the second year that the plants show their true character. They not only send up a greater number of flower spikes, but the individual blossoms are increased. The seed is very small, and therefore requires to be sown in a fine sandy soil, and to be very carefully watered. Where bottom-heat is available the seed-pan should have the benefit of it. As soon as the seedlings are large enough I prick them off into another pan, and keep the soil about them just moist, and out of the reach of the sun. A sheet of glass laid on the pan and a piece of paper to afford shade in bright weather supplies the most suitable conditions for the seedlings. Even as the plants get older the leaves retain a better colour if a thin shade is put on the glass during the hot summer months. It is a misfortune that the foliage cannot bear strong sun without losing the dark-green colour that they retain when grown in the shade, because I find the leaves get drawn out unduly in length, which somewhat detracts from their otherwise charming appearance. It is a mistake to give the plants large pots the first year. I find those 4 1/2 inches in diameter quite large enough. In the matter of soil these plants are not very particular. My stock is growing in an ordinary mixture of garden mould, leaf-soil, and sand, and they were in flower nearly the whole of last summer. Being herbaceous in character, the soil about the roots must be kept constantly moist, but they must have more root waterings in summer than in winter. I am afraid the Streptocarpus

3447.—Failure of a hot-bed to heat.

No doubt the manure was trodden in the pit too firmly, hence the failure. This is plainly proved by the fact that when thrown out loosely on the ground fermentation at once set in. Fresh litters stable-manure alone might have heated all right, even to the pit, but pig and cow manure I always look upon as nasty cold "soggy" stuff that is not fit to form part of a good hot-bed. If you could add an equal part of tree-leaves collected last autumn, or, better still, of fresh tan to the stable manure, you would secure an excellent and lasting hot-bed.—B. C. R.

3395.—Azaleas after flowering.

If your plants are of a good shape they require no pruning. Allow the young growth to gradually harden off in a cool, shaded spot in the greenhouse. When quite ripened you can then put them outside on a warm, sheltered border. When the flower-buds show remove them again to the house. In this way you should have good blooms next year.—S. J.

—The plants have to make their growth after flowering, and should be placed in a warm house to do so; water and syringe freely. Do not cut them down; they require no pruning. If there is not a heated house, encourage them to make growth in the greenhouse. When growth is made and buds formed they may be turned out-of-doors.—J. D. F.

3380.—Ants in a stove.—To destroy these mix arsenic into a solution of sugar and water, which they will devour greedily; but care must be taken that no other animal gets to it. Cover the saucer with a slate on the top of it, having a couple of pegs between the saucer and slate to let the ants in.—M. J.

3382.—Treatment of Azalea Mollis.

—If Azalea Mollis is cut back after flowering, there will be no blossoms the next year. A strong, rambling shoot may be cut out, but there should be no regular cutting back. The reason why Azalea Mollis fails to bloom is owing to the neglect to which they are exposed in placing the plants outside before the wood has had time to harden. If they are kept indoors in the same way Indian Azaleas usually are, till the wood is getting formed at the base, they would flower annually.—E. H.

—If the plants have been grown for forcing they may either be put in flower-pots for the summer, or be planted out in the open garden in good peat soil. The question is asked, "Should the shoots be cut back to 3 inches or 4 inches, and then be planted out?" Presuming that it is the plants that are to be planted out, and not the shoots, I may say they are least trouble when well planted in peat soil; but the plants must first be nursed to the open air by being kept for some time in an airy, light greenhouse. It

Economy in heating.—I am heating two houses, each 20 feet by 12 feet, with an expenditure of not more than 1s. per week during the recent severe weather. I use refuse coke from the gas works, which costs cartage only. I have a big saddle boiler over a good-sized fire-place. This heats the pipes which supply the

is best not to prune them at all; the plants become bushy enough without it. They may also be grown in flower-pots during the growing season; but it may be necessary to shift them into larger flower-pots, and they require a good deal of attention during the season. They do best out-of-doors, and, if well cared for, will set a large number of flower-buds.—J. D. E.

FRUIT.

FLAVOUR IN FORCED STRAWBERRIES.

There are many who object to forced Strawberries, owing to their being flavourless and deficient, to a great extent, of that fine aroma and full flavour outside fruit obtains. I fear this want of flavour, in early fruits especially, has often deterred employers from forcing largely. The Strawberry when forced slowly and provided for dessert in May and early in June forms a welcome addition to the somewhat limited dessert obtainable at that date. If carefully ripened it is very little inferior to fruit from the open. Many years ago the question of flavour did not receive the same attention as it does now, as I cannot remember a single instance where the plants were removed to a cooler house. In many instances the fruit was ripened in Pine-houses, and no thought was given to removal, lowering of the temperature, or more air. I have heard it remarked that we have made great strides in new varieties that are of quicker growth and less liable to insect pests, but I have not found it so. If tied to three varieties, my selection would include two of the oldest and, I feel sure, the most reliable. In Strawberries, as in other fruits, there is a wide difference in quality, and as quality and flavour should be the first considerations for the private grower, he will not have so wide a selection as the market grower, with whom size and colour are everything. In very early forced fruits it is almost impossible to get both these qualities—viz., size and good flavour, so that to some extent gives the early fruit a bad name, as large fruits are sadly deficient in flavour, and small ones are objected to on account of size. Early in March I saw some fine ripe fruits that had been produced at some cost. They were flavourless, whilst fruits of the smaller Vicomtesse d'Harcourt do Thury were of excellent flavour, and the weight in the aggregate equal. If flavour is desired in early fruit, size must not be the first consideration. Of late years the large growers (to some extent) have wisely given up very early forcing and do not get the Strawberries ripe till late in April or May. By so doing, the larger fruiting kinds, which are best for market, and when sent in good condition in the season find a ready sale, can be grown. The large grower uses what are termed Strawberry-houses, which are generally filled at once, so that when the fruit is ripe or nearly so a lower temperature is maintained. This improves the flavour of the fruit, and causes it to be firmer for travelling. In many gardens it is not always practicable to give a whole house to Strawberries, but late in the season cold frames may be utilised and the flavour of the fruit much improved. I am aware of the labour this involves, but I question if it is much greater in the end, as the plants when removed to a cooler house or frame absorb less moisture, the fruit keeps longer, and the hotter house may be put to other uses, while there is less discomfort in attending to the plants. The question of moisture is a wide one, and often is the chief cause of the want of flavour. I do not like the saucer system, as it causes the fruit to be insipid. Saucers are no doubt good as far as labour saving is concerned, but if there is a spell of dull weather the flavour of the fruit is much impaired. I prefer to see trays placed on the shelves or standing specs, Grass-side downwards, as these check the loss of moisture and prevent flagging in hot weather. There are also various means to prevent dryness at the root. I have a thin board to shade the front of the pots, and covered the shelves in some instances with Cocoa-nut-fibre or decayed leaves where it can be done without being untidy in the house. In frames the pots may be partially plunged in the cool material and much labour saved. Whatever material is used, the drainage should be perfect to allow the water to get away freely. If only a few plants are grown, a hand-dug

second pot a size larger, placing the fruiting-pot in the empty one, this keeping the roots cool and preventing evaporation. When late fruits are grown in frames, much can be done to get flavour by the giving of air and attention to moisture. Liquid-manure should be omitted at the right moment, as this greatly deteriorates the flavour of the fruit. If it is impossible to lower the temperature when ripening commences, it will well repay the cultivator to remove to a cooler house, doing the work carefully so as not to bruise the stalks or fruit. G.

3432.—Peach tree losing its flowers

—When questions are asked they ought to be more definite. In this case not a word is said about the conditions under which the tree is growing, nor whether it is in a Peach-house or on a wall outside. It is in a Peach-house probably, and the blossoms drop because the tree has received a check of some kind, and this is more likely to happen when the tree is growing under glass. If the house is kept too moist, and shut up when in this state, the blossoms will drop; an overdry inside border will also cause the blossoms to drop off. My plan with Peach-trees when in blossom is to keep up a rather warmer atmosphere, and as dry a one as possible; admit plenty of air by day, and do not shut up the house altogether even at night. The pollen should also be distributed with a camel-hair brush from the anthers to the pistil.—J. D. E.

—The variety named (Late Admirable) does not always ripen its wood up well, and then the flowers drop. I have occasionally had thin crops from this cause, and I think this variety should have a warm, sunny position. I cured one tree of this bloom-dropping by moving it to another spot, where the border was dryer, and the tree had more sunshine and warmth. A dressing of lime on the border will probably do good.—E. H.

—It is well known that in the case of some sorts of Peaches bud-dropping is an inherent failing; but as far as my observation goes it is not so with the sort you mention, and it is one of the oldest of Peaches. You say that the flowers are fully expanded, which indicates that the cause arises from something unusual—either from the want of root-moisture or a state of debility in the tree that is not easily traced. As you do not give the age of the tree or state whether it is under glass or in the open, you increase the difficulty of giving a more definite answer.—J. C. C.

—This variety is not addicted to dropping its flower-buds as a rule. Dryness at the roots during the winter is the primary cause of this defect, although a too warm atmosphere at the same time will contribute to a loss of bloom. There is still another cause—excessive growth made during the summer; in consequence the wood is not matured.—S. P.

3433.—Grub on Apple blossom.—The grub is the larva of the Codlin-moth, and though it may be difficult to clear off altogether perseverance will soon thin its numbers. The trees should be sprayed with the garden engine when the Apples are quite small, at the time the moth lays its eggs in the eye of the Apples, usually early in June. Paris Blue or London Purple is much used for this purpose. These are preparations of arsenic and lime mixed with water, and are mainly used because the ingredients are cheap and not difficult to apply. But there are other things which may be used effectually. An insecticide called the Gardener's Friend, which forms an emulsion in water, I have found very useful. This also is cheap, and cleanses the trees effectually where it goes. Besides spraying twice in early summer there are other means which should be adopted. Many use grease-bands to prevent the insects crawling up the stems of the trees to secrete themselves in winter. Hay-bands may be wrapped round the stems of the trees to form hiding-places for them, to be afterwards removed and burnt with the insects before they change their condition, and lastly, all fallen Apples should be gathered and used or destroyed as soon as they drop, before the insect has time to crawl out. The maggot eats its way to the centre of the Apple, and when the vital part is reached the Apple falls, and the insect eats its way out, and seeks fresh quarters.—E. H.

The Apple is exceedingly liable to be injured by various maggots and caterpillars which destroy the fruit. The Apple is also

(*Teuthreda testudineae*) deposit its eggs in the Apple-blossoms; but there is no way to prevent it from doing this. The only remedy is to collect the fallen fruit, which drops off owing to the larvae feeding on its interior. It falls from the trees when about the size of a Walnut, and the best plan is to collect and burn it. Another troublesome pest is the Codlin-moth, which deposits its eggs in the young fruit. The grub is speedily hatched, and sets its way into the interior of the Apples, causing them to drop off in the same way as the larvae of the saw-fly does in this case also. Destroying the Apples is the best remedy. As this species spins itself a cocoon on the bark of the trees it is a good plan to keep them free from loose bark. The cocoons would be found in June.—J. D. E.

3434.—Fruit-trass on Oak-paling-fences.—Pears and Apples would no doubt do well on the fence facing east, and Plums and Apples on the west side; or if you like more variety you may have some Cherries on the last aspect. May Duke and Bigarreau are two useful Cherries. I do not think the draught will do serious harm to the blossoms. If I wished to plant Pears in such a case I would select triple cordons, and lift and replant the trees the third year after planting. Even single cordons would be better than fan-shape or horizontal-trained trees.—J. C. C.

—Plums would succeed best with an eastern exposure, such free setting kinds as Victoria, Orleans, Jefferson, Cox's Golden Drop, Kirke's, and Prince of Wales, would be a good selection, as, with the exception of Orleans, none are extreme early, and in consequence would escape the cutting winds sometimes experienced when in bloom. Apples and Pears would be preferable for a western exposure; of the former, fresh Peach, Lady Sudeley, Cox's Orange and King of Pippins, are good dessert, while Lord Grosvenor, Echlinville, Warner's King, Stirling Castle, and Laue's Prince Albert, are suitable and free bearing kinds in the kitchen section. Free growing and heavy cropping sorts of Pears are Jargonelle, Louise Bonne de Jersey, Doyenné du Comice, Marie Louise, and Pitmaston Duchess. Both the Apples and Pears should be espalier-trained, while fan-shaped is best for Plums.—S. P.

3445.—Pear "Bishop's Thumb."—I have known this Pear for a number of years, and frequently see it growing as a standard in market gardens. But I never knew or heard of its behaving in the way this correspondent describes. It is as opposite, in fact, to what I have been accustomed to regard it, that I can hardly think it is the same sort. A friend of mine has many bushels of fruit of it to dispose of every year from standard trees, and he regards it as one of the most profitable of second-rate market Pears, as it always pays him for finding store room for the fruit for two or three weeks. Whether "N. Y. Z." has got the true sort or not does not matter much; the trees, whatever the sort may be, are not worth keeping, and should be rooted out.—J. C. C.

3441.—*Tropaeolum tuberosum*, &c.—This is a distinct plant from *T. speciosum*. The last named was introduced from Chili in 1846, and may be propagated from seed sown in a frame in a little bottom-heat, or by dividing the underground rhizomes. It likes a moist and rather shady position in a border of peat-soil. The flowers are scarlet, and it has been named the Flame Nasturtium. It is a hardy plant, but *T. tuberosum* from Peru is not more than half-hardy, and produces red and yellow-coloured flowers. It forms tubers at the root, hence its name. Propagate by division or seed.—J. D. E.

—*Tropaeolum tuberosum* is quite distinct from *speciosum*. The former is the Peruvian Nasturtium, and has tuberous roots. The flowers are yellow and red, and it has larger leaves than *speciosum*, which is known as the Flame-flowered Nasturtium, owing to the intensity of its scarlet colouring. The former is easier of growth than the latter, succeeding in almost any position, while the latter prefers a cool site for its roots. For instance, the northern side of a high wall or hedge, or even that part of a shrubbery, over which the long trailing shoots will ramble. In any kind of good garden soil both sorts will flourish.—S. P.

THE KITCHEN GARDEN.

EARLY PEAS.

THERE are many expedients resorted to in order to hasten the growth of early Peas; but there is no way, except growing the very dwarf sorts under glass, that has yet produced Peas in quantity more than a few days in advance of those sown in well-sheltered positions in November, protected from mice, birds, and slug. By-the-way, a good protection for the

Fig. 1.—Pea "Laxton's William the First."

Peas against the ravages of the two first-named pests is to sow the seeds on a flat surface, and cover them first with chopped Furze, and then mound the earth over the rows, using a covering of soil over the young tops when they begin to show their green points through the ground. To prevent the depredations of slugs, a good dusting of sifted asbes, or chaff from Barley, is often used with good effect. As a precaution against the possible failure of these early Peas, I have usually sown a good quantity during January on strips of turf, cut 1 foot long and 3 inches wide. These, turned Grass-side downwards, are packed closely together on stont planks; the middle of each turf is then scooped out, and the Peas sown and lightly covered with fine soil. A cool vinery snits them admirably until the shoots are 2 inches or 3 inches high, when they should be transferred to cold pits and hardened off by exposure, so as to be fit for planting out the first or second week in March. As the roots will be found hanging through the turves in quantities, wide drills should be drawn, and each turf should be carefully replanted. The rows should then be staked at once, and light evergreen branches should be placed a short distance from each row, for the purpose of breaking the force of the rough winds that usually prevail at that season. On a south border, thus planted, Peas in quantity may be generally gathered about the last week in May. Two of the very best early kinds are the following varieties—namely, Sangster's No. 1, a white Pea (also known as Ringleader and Prince Albert, and by some thought to be identical with Daniel O'Rourke) and Laxton's William the First (see Fig. 1), a very fine kind, not quite so early as Sangster's No. 1, but superior to it from the fact that it produces Peas of a fine green colour

and excellent flavour, and it also continues bearing for a remarkably long time. A good Pea to sow to closely follow on after the earliest kinds is Laxton's Supreme (Fig. 2). H.

KIDNEY BEANS IN POTS.

CONSTANT supplies of Kidney Beans are indispensable in numerous cases, and being fully appreciated as an extra choice vegetable, private gardeners do not, as a rule, begrudge the amount of labour and valuable space necessarily devoted to their culture. It is my firm belief, however, that they are not nearly so liberally treated as they ought to be, the consequence being a rather weakly growth, a plentiful supply of red-spider, and light crops of Beans. No amount of overhead syring and atmospheric moisture will prevent the spread of red-spider over half-starved plants, and at least a third of the pods that show on starvelings turn yellow and drop off. In my younger days I have three-parts filled hundreds, I may say thousands, of pots with very poor mixtures of soil—anything being thought good enough for Beans—and when the plants were high enough for staking this was done, a top-dressing of fairly rich compost being given at the same time. Similar treatment is common enough at the present day, but it is not worthy of being designated good culture. The Beans are simply starved before the top-dressing is given, while the latter puzzles or misleads those who water the plants, and is of little real service in any case. Instead of using such poor soil it pays well to give the Beans a compost consisting of two-parts of light loam—if fibrous so much the better—to one of flaky manure or old Mushroom-bed manure, adding a sprinkling of lime-rubbish, wood-ashes, and well-charred garden refuse. The requisite number of 9-inch pots should be nearly filled with this light compost, pressing or jarring this down only moderately hard, from nine to a dozen seeds being sown in each, and covered with about 2 inches of soil. Enough space should be left for watering. Crowding the plants is unwise, and the number should early be reduced to about seven in each pot, these being lightly staked up before they are far advanced in growth. The best places for these Beans are the back shelves in three-quarter span-roofed forcing-houses, and the walls and front stages or beds in the fronts of similar houses, a strong beat and plenty of light being desirable, though they can be brought on slowly, but profitably, from this state in intermediate temperatures. When a tempting compost is provided, the roots quickly overrun this, while the plants grow healthily and sturdily, quickly coming into full bearing. Before they give signs of requiring liquid-manure, soot-water, answering well at first, should be given, and when the pods are growing the plants should be fed up daily, never once being allowed to become dry at the roots. Thus liberally treated, they retain a healthy, clean appearance up to the last, and the crops are most satisfactory. Mixing a little lime instead of lime rubbish with the compost has frequently been tried with good results, this apparently causing a more sturdy growth, the leaves of the plants being of a dark-green hue, while the productiveness is all that can be desired. M.

3375.—Potato disease.—The following particulars may be of value to "Carter." I think that sulphate of copper will be much used in the future for the prevention of Potato disease. Here are a few facts. Last year an important experiment was carried out by Messrs. Carter and Co., of High Holborn, and this plan of meeting the Potato scourge has been so satisfactory in France that the great French chemist, Dr. Aimé Girard, says the mixture may be confidently recommended as a preventative of the Potato plague. Messrs. Carter planted about an acre with Potatoes in ten double rows, the drills 3½ inches apart, as plenty of light can then get to their branches. The kinds planted were Myatt's Ashleaf, Snowdrop, Beauty of Hebron, and others, the whole piece of ground being divided into four equal parts, of which the first and third were dressed with the Bouille Bordelaise, and the second and fourth left undressed. The strength of the mixture was as follows:—22 lb. of sulphate of copper, 22 lb. of unslaked lime, and 100 gals. of water, this

being the quantity necessary for an acre of Potatoes. The sulphate of copper was of 98 per cent. purity, and the Macclesfield patent sulphate of copper, the same as used so successfully by M. Girard. The first and third quarters were dressed with the Bouille Bordelaise on July 11th and August 2nd, and the second and fourth left undressed, the mixture being applied thoroughly on both surfaces of the leaf. The disease appeared early in September in the undressed portions, and when lifted it was found that, as far as some tubers are concerned, the yield was about 2 tons per acre more than in the undressed portion (the two plots being less than half an acre). Another noticeable feature is that the quality of the tubers was better. I saw the experiments and vouchsafe for the accuracy of the above particulars. I think that the Bouille Bordelaise will be much used in the future as a preventative of Potato disease, a pest that has for years engaged the attention of Potato growers and others.—C. T.

3435.—Constructing a Tomato house.—Why do you not state what kind of house you are building? As there is a "walk through the centre," I presume it is a span-roofed structure, but you give no guide as to the height or width. If above 12 feet in width, I should advise you to have two pathways, with a narrow beat to take a single or double row of plants on each side, and a wider one in the middle. As a rule, I like to see the beds in a Tomato-house raised about 1 foot above the level of the path, but it does not greatly matter; in some cases the plants are set out on the floor level—in the ground on which the house stands—and in others on beds raised more than a foot; in either case

Fig. 2.—Pea "Laxton's Supreme."

with good results, if the treatment is right. As regards the arrangement of the pipes bottom-heat is quite unnecessary, and, as a rule, the best place for the pipes is along the sides and the ends of the house, next the glass or outside walls. Unless very early fruit is wanted, a single row of 4 inch piping all round will warm a house not exceeding 12 feet in width, nor 7 feet in height, quite sufficiently; but two rows of the 3-inch or 4-inch size would be better, of course, and if the structure is wider or lofty, two or three more rows might be fixed along the

pathway, or ways, with advantage. Provide plenty of large ventilators both in the roof and along the sides.—B. C. R.

—The height of the inside beds should depend on the height of the side-lights, if any. Supposing there are no side-lights and that the roof rests on a wall 2 feet above the ground line, with ventilators fixed in the wall, the height of the beds need not be more than 9 inches or 1 foot above the level. The hot-water pipes should be placed round the sides close to the wall, and the top pipe about 6 inches from the glass at the highest point. If you intend the house to be any use this season for Tomatoes you must push on the work with all possible speed.—J. C. G.

3425.—Growing Salsafy.—This requires about the same treatment as Carrots, and should be sown now in drills about 12 inches apart, to be thinned out when large enough to 6 inches apart in the rows. The land should be deeply cultivated, but not freshly manured, or the roots will fork out and be of little value. Salsafy forms a good rotation to Celery, the old manure in the trenches being thoroughly blended with the soil of the intervening spaces.—E. H.

—Salsafy is an easily cultivated plant; but to do it well it requires a very rich soil and a fairly open position in the kitchen garden. The plant produces long tapering roots, and requires soil trenched about 2 feet deep. Sow the seed in March or April in shallow drills made with the corner of a draw hoe. Sow very thinly, as the plants have to be thinned out to 8 inches or 9 inches apart in the rows. There is no more trouble in cultivating them than there is in growing Carrots or Parsnips. The roots are ready for cooking in October, and may be used during the winter; but it is desirable to dig some up in November, and put them in sand in case a hard frost sets in. The roots left in the ground can be used in open weather and in the spring.—J. D. E.

—This excellent vegetable must not be sown too early, or the plants are very liable to run to seed the same season, and if this occurs the roots become woody and useless. The best time to sow is probably the third or fourth week in April, and then, as a rule, very few of the plants will "bolt." The soil must be deep and moderately rich, the best way to make a good bed being to trench it 2½ feet deep the previous autumn, working in at the same time a fair amount of well-decayed manure, but chiefly towards the bottom of the trenches, or the crop may be grown with good results after Celery. In any case, no manure ought to be applied for some months before sowing the seed, or the roots will fork. A liberal dressing of burnt soil on or near the surface will ensure a rapid and healthy growth. Sow the seed rather thinly in drills a foot apart and an inch deep. When the seedlings are about 3 inches high thin them out to 6 inches or 8 inches apart, the latter distance if roots of the largest size are required. Keep the surface free from weeds, and, at the same time, in an open, friable condition by the frequent use of the hoe between the rows, and, if possible, the bed should be watered occasionally in dry weather. The roots will be fit for use in October and onwards.—B. C. R.

3471.—Good King Henry.—In GARDENING, March 11th, "A. G." asks whether the leaves or the roots are used for cooking? The roots are not used. The stems and leaves together are cooked and used in precisely the same way as Spinach, and are of excellent flavour, or the thick stems tied in a bunch may be cooked in the same way as Asparagus. As regards the time when it is in season, that extends over a long period with a little contrivance. This is what I have done for several years, with a bed of three rows 18 inches apart, and 15 inches between the plants: I commence at one end of the bed, early in January, with a dozen 12 inch plant pots, placed upside down over the first dozen roots; then cover the pots with fresh stable-manure to the depth of 3 feet, so as to form a good hot-bed, and by the beginning of February I have some ready for use which is blanched and beautiful. The next portion of the bed, on which I set a Cucumber frame with glass, is ready for use now. Then comes the last portion in the open air, which will last till other vegetables are planted. HENRY JAMES, *Belfast*.

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

YOUNG plants are now making rapid progress, and if a successful flowering period is to be the end of nearly a year's work, they should on no account receive a check in their early stages. Therefore, promptly give the later struck—and, in fact, all which by the quantity of young roots show that they require it—a shift into larger pots. At this time of the year they quickly get pot-bound. Many a promising lot of Chrysanthemums has been stunted through the potting being delayed even a week after the plants have reached the proper stage, when the roots want more room. It is not safe, perhaps, in any locality to stand the plants entirely out-of-doors thus early in this month, but still they ought now to be treated as slightly protected hardy plants. The lights may be taken off during the day and only returned at night, and to ward off heavy showers of rain or cold, cutting wind. Exposure and sun may cause some of the leaves to flag a little; but this will do no harm, and I would not advise sprinkling the plants in the middle of the day to prevent it. I have had the leaves scorched from no other cause than this in my anxiety about the same looking a bit distressed. Nor do I favour syringing the plants from this time; there is always plenty of moisture about them through watering in the ordinary way. Especially in low-lying districts should excessive moisture be avoided. Mildew generally comes soon enough without aiding its advent. Green and black aphides are sometimes troublesome at this season, but they are easily killed by a dusting of Tobacco-powder. The same powder will also destroy thrips, which in some collections do a great amount of harm. It is well to wash this off with the syringe the morning after using it overnight before the sun reaches the plant. As overcrowding is a prevalent error in plant cultivation, it may be timely to again mention how advisable it is that young Chrysanthemums should have plenty of room to grow, light and air playing among them being so essential to success. Continue to pinch out the tips of the shoots of those plants that are to make bushes, and place a little stick to those that are to have one stem. A point in connection with the latter is the number of flowers that each plant should carry. The orthodox number appears to be three. In a former note I named a few kinds that pay for cultivating for the small number of one, or at the most two, but I am equally well satisfied that in the case of many sorts, especially of the Japanese varieties, better results than obtain would follow if each plant were allowed to perfect from four to six flowers. I believe that I am right in saying that many ill-formed buds owe their origin to growth that is concentrated upon too few shoots. Size of blossom is so much in our thoughts that strength in the plants is overdone. The same as in animal life, however, hardly two Chrysanthemums have a like constitution. For example, Sunflower, W. H. Lincoln, M. Bernard, Gloire du Rocher, Puriton, Violet Rose, E. Molyneux, Avalanche, W. W. Coles, Mlle. Marie Hosts, Meg Morrillies, Bouquet des Dames, to name a few, cannot well be grown too strongly, and the three flowers may be quite as many as the plant will bring to perfection. But on the other side may be named such excellent sorts as Viviani Moral, Florence Davis, Etoils de Lyon, A. H. Neve, Stanstead White, William Trioker, Mme. John Laing, Sarah Owen, Anna Hartzhorn, which must not be overdone. I take this as a guide in the case of a new variety. If it possesses in its what may be called ordinary or undeveloped state an extra number of florets, and in all cases comes full to the centre, then allow plenty of shoots to grow, but if the opposite to this show itself, concentration must be the order of the day. In this matter of incurved sorts again, three blooms have been the number for each plant to carry, and believed in so long, that one almost seems afraid to recommend a larger number. However, I have for some time observed the ways of the Chrysanthemum in other collections as well as my own, and have often noticed in a plant, say, of Empress of India, that the weakest shoot supplies the most comely bloom. It is exactly the same with the family of incurved sorts that have sprung from the

variety Princess of Wales, most beautiful flowers certainly. I always attempt to get strength and substance in the plant by striking early and so on, but allow each to give from four flowers, otherwise a bud will contain too many florets to develop a perfect bloom. Some of the incurved class, which must, however, have strong shoots to get anything approaching a large and full flower, are the Princess of Teck family, Barbara, Golden Eagle, Refulgens, Nil Desperandum, Mr. Brunceles, Princess Beatrice, Novelti, Mr. Bann, and so on. The new class for thirty-six distinct incurved Chrysanthemums, which will appear in the schedule of the National Society this year, will no doubt induce some growers to cultivate again old sorts that have been discarded. This is well, perhaps, for, although small, many of the kinds of past days are pretty. Among them may be mentioned Aimée Forrière (ronsemed Mms. Gayral) (white, tipped purple), Baron Beust (chestnut-red), Chernb (orange-bronze), Isabella Bott (pearly-white), Lady Carey (rosco-lilac), White and Pink Venus, Nonpareil (lilac), Beauty (blush-pink), Eve and Mabel Ward. H. S.

3444.—Chrysanthemum cuttings.—The plants are making their first natural break, although it is early. So much depends, however, upon the manner in which the plants have been grown. If in their early stages they were kept rather warm, or if the growth has been in any way drawn up through want of light, or a sufficiency of air to keep them stocky and backward in their growth. All these matters of detail tend to hasten or retard the first natural break, as the case may be. As "E. H. P." speaks of the three shoots formed below the bud, it appears to be simply a case of premature growth, and not, as he fears, persistent bud formation. Pinch out the flower-bud at once, and all growths but three of the most promising. These are generally those nearest the point where the flower-bud formed. By removing promptly all surplus shoots as well as the bud, the whole energy of the plant is concentrated in the selected three shoots. Place a light stake to the plant, securing loosely, yet firmly, the three shoots to prevent an accident. Should any of the plants show a flower-bud in the point of the shoot and give no prospect of new growths being made from the nodes below, cut the plant down to within 4 inches of the soil, and take up another shoot from the base.—L. M.

3445.—Height of Chrysanthemums.—It is difficult to say what height the plants will grow when managed as bushes by topping them twice, as so much depends upon what they are topped and what height they are allowed to grow before topping them. The position which the plants occupy during their early stages of growth has much to do with the height of the plants also. If they occupied a position somewhat dark, or a distance from the glass in the greenhouse, they would naturally grow taller than though they had been kept close up to the glass in all stages. It is much easier to give the approximate height of the plants when they are cultivated on the large-bloom principle. If "W. D." intends topping them twice, I should advise that the first take place at 4 inches from the soil, repeating the topping when 5 inches more growth is made. Presuming that pots, 9 inches in diameter, are employed, the plants will grow something near the undermentioned height: Mons. Bernard, 3 feet; Sourco d'Or, 4 feet; Bouquet Fait, 5 feet; W. Robinson, 5 feet; Roseum superbum, 4 feet 6 inches; Maiden's Blush, 5 feet; Val d'Andorre, 3 feet; Pstoe the Great, 4 feet. The Pompons and Anemone Pompons named will grow on an average 3 feet high. Pots 8 inches in diameter, inside measure, will suffice for this section. Porter's wire-woven crocks are the best preventive of worms entering the pots. Place one at the bottom of each pot, adding the ordinary quantity of drainage beside. Should any worms find their way into the soil, however, lime-water will cause them to come to the top of the pot by soaking the soil thoroughly once. Place a handful of quicklime in a 3-gallon can of clean water, well stirring it, and allow it to settle. If the limes does not settle to the bottom of the water, but is held in suspension, and porous, it cannot be made too strong, because the water cannot contain more lime

thao a certain quantity, which is harmless to plant-life. Be careful, however, not to stir the water when applying it, but pour it on gently, leaving the sediment at the bottom. If one dose does not remove all the worms, give another in ten days.—E. M.

3434.—**Early Chrysanthemums.**—The following varieties will be found to succeed out of doors, but the manner in which the plants are managed, and the weather experienced during the month of August and September, will much determine whether all will flower before the end of the latter month or not. They all will before the middle of October, at any rate. The best way to treat the plants is to allow them to grow without any topping of the shoots whatever. In this manner they will flower earlier than though the points were pinched out of each once or twice. Should the weather be hot and dry during the summer, the plants will derive much benefit from copious supplies of water and occasional doses of liquid-manure, not too strong, and a light mulching of

PROPAGATION OF TREE PÆONIES.

In reply to "J. R.," "S. J.," and "Brixtonian," these are generally propagated by grafting on the stout, fleshy roots of the herbaceous kinds. Increased in this way, plants make much more rapid progress, especially during their earlier stages, than do those that are raised from cuttings. The present season is very suitable for grafting; indeed, from now till the end of August is the best time of the year for carrying out this operation. The most suitable stocks are any of the numerous varieties of *P. albiflora*, and all that is required is to take the tuber (leaving on it as many fibrous roots as possible), and having fashioned the scion in the form of a wedge, the upper part of the fleshy root must be split for a certain distance, and the wedge-shaped base of the scion inserted therein. It must then be tied securely in position, and the point of union covered with grafting-wax in order to render all air-tight. Of course, in inserting the graft in position, care must be taken that the bark of

planted out or potted into larger pots. During the winter care must be taken not to overwater them; indeed, they will require very little water while dormant. Layering is also another way by which Tree Pæonies can be increased, but of course it can only be used where there are good-sized specimens, from which a few branches can be readily spared. This operation is best carried out in the autumn, when the portion of the branch that is to be buried must be partially cut through, and a tongue formed as a nucleus from which the roots will spring. The branch must be held firmly in position by a peg or pegs, and if the soil is attended to in the matter of moisture roots will be formed the next season. Besides these methods, when a plant is established on its own roots it can often be split up into several pieces, leaving sufficient fibrous roots on each to support it. Seeds seldom ripen in this country, but when they are obtained no time should be lost in sowing them, a good soil for the purpose being an open, sandy loam. After sowing the seeds they should be

OUR READERS' ILLUSTRATIONS: Tree Peony at Eston Lodge, Monkstown, Co. Dublin. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. Greenwood Pim.

partly-decayed manure spread on the soil for about 1 foot wide around the plants. This keeps the roots cool during dry weather, and arrests the evaporation of moisture from the soil. Mme. C. Desgrange, white; G. Wermig, pale-yellow; Mrs. Hawkins, rich yellow; Lady Fitz-Wygram, white; E. G. Anderson and Son, golden-red, reverse crimson; Bouquet Estival, deep-rose, reverse silver; M. E. Pynaert Van Geert, yellow, striped bright-red; Lady Selborne, white; Isidore Fereol, rose-lilac; Grace Attick, white; W. Holmes, rich-crimson-brown; Mme. la Comtesse Foucher de Cariel, red and orange.—E. M.

3427.—**Rabbit-manure.**—I should say that rabbit-manure is not good for flowers or anything else. I have never used it, but from what I have seen of its influence on Grass where these creatures abound in a wild state, it certainly does not point to its possessing any manurial value, but rather the other way, for Grass refuses to grow where there are many of their droppings. A tablespoonful of soot mixed with a pint of soil would be a safer stimulant to use.—J. C. T.

both stock and scion fit perfectly; and should there be a very great difference between the two in size, the wedge-shaped portion of the scion may be so fashioned that an exact union is effected only on one side. The most suitable grafts are the good clean shoots without flowers, although when any particular variety is required in quantity the shoots that have flowered may also be used for the purpose. After grafting, these Peonies must be potted sufficiently deep in the soil to completely cover the point of union, and for some it will be necessary to use pots deeper than the ordinary size, as the thick fleshy roots will prevent the plant being buried low enough in the soil. After this is done they may be placed in a close frame, and care must be taken not to overwater till a union is complete, which, generally speaking, will occupy about a month. No heat is needed for carrying out this operation successfully, but the plants must be carefully attended to in the matter of shading, watering, and other particulars. After a union is complete the better way is to leave the plants in the frame till spring, when, after the danger from frosts is over, they may be

placed in a frame, where they will lie a long time before germination takes place, and as their rate of progress afterwards is by no means rapid, it is necessary to wait several years before they flower. The accompanying illustration shows a fine old specimen of Tree Peony in flower. G.

3391.—**Liquid manure.**—Bedroom slops would hardly suit; in fact, would be in every way objectionable. If you have absolutely no space to keep liquid-manure in, you should get some good, well-decayed manure a week or ten days before you want to use it. Soak it in water, say a gallon of water to a good shovel-ful of well-rotted manure. Keep it occasionally stirred until fit for use. The solids left in the mixing-tub can then be dug into the ground if wanted, more or less water to be used as strength is wanted.—S. I.

3390.—**Anemones from seed.**—Sow the seed now in boxes of fine soil, and when the young plants have grown a little prick them out in boxes or in a border 3 inches asunder. When the leaves decay dig up the small tubers and plant them again in October. They must be under glass to sow in February or March.—J. D. E.

OUTDOOR PLANTS.

PYRETHRUMS.

It does seem somewhat odd that such very hardy herbaceous roots as are Pyrethrums should yet be so impatient of division and even of removal. Ordinarily all such roots may be divided with ease and safety. These particular plants, however, are exceptions, and need very much care in their winter culture; still, it is far from being difficult to increase stock once the varieties are established, by taking off some of the young growths early in the year and putting them singly into tiny pots, rooting them quickly in a little bottom-heat, and thus ensuring in that way not only an abundant stock, but a constant supply of young plants. When such is the case, it is not worth while to trouble about the retention of very old roots, which may in such cases be dispensed with. Shoots invariably break up rather more thickly from well-established roots than is desirable for retention, and therefore the thinning of them out for the purpose of propagation is good at once to increase stock and to give stouter growths for producing flowers. But it is not easy for the most enthusiastic fancier of these hardy flowers to keep pace with raisers of new varieties, even if thought desirable. Possibly any beginner in the cultivation of Pyrethrums would find it difficult enough to make the best selection of a score of double and the same number of single forms out of such a stock as even Messrs Kelway and Sons have, for their catalogue over 100 double and nearly as many single sorts, whilst other raisers have sorts in abundance. A good selection from any list is not easy, because the differences between one and another or between one score sorts and another score is perhaps trifling. The real advance made in Pyrethrums is not to be measured by comparing one variety with another so much as by contrasting what was the best of twenty years ago with the best of to-day. It is especially interesting to find how in that time single forms have become popular. It is very probable that, as a rule, they are more so than the double forms are, for after all a double Pyrethrum flower is not one of the most pleasing or attractive forms, especially for what is termed domestic decoration, much as they may be in favour with those whose chief notion of the value of flowers is that they are of rotund form, very enduring, and good for exhibition. The single Pyrethrums have given to us in their large Daisy or Marguerite hoods colour so charming, that they almost resemble Paris Daisies artificially coloured, for it is difficult to tell them from the popular Marguerites, except by their colours. One particular advantage found in having young plants from cuttings put out every year to bloom is that they not only flower later than do old plants or stools, but may be still later if the flowering-stems be pinched when half grown, so as to encourage the throwing out of side flowers, which, if smaller than are the ordinary ones, are not the less welcome because the bulk of the blooms is over. Pyrethrums like a deeply-worked and fairly holding soil, well manured, and very clean. Each winter a top-dressing of short manure, lightly forked in, will be productive of much good. It is, however, perhaps best to leave the addition of dressings of this sort until after the needful stock of cuttings has been taken from the stools. The plants should have ample room, as the growths spread widely if not unduly bunched in the tying up. A.

3387.—**Violets for outdoor culture.**—Violets deserve to be well cultivated, and this must be if very fine flowers are desired. The position for the plants should be open, and the soil fairly light, not too rich, as upon very rich ground they run to leaf, and bear very few flowers. If the soil is heavy it must, therefore, be lightened by the addition of gritty material, such as roadside scrapings. This is a very good season to plant, finishing the work before April is over, but the earlier the planting is done the better, as then the plants get well established before they are likely to suffer from hot and dry weather. The rows should be one foot apart, and the plants nine inches apart in them. Take care to make a good commencement by having strong, sturdy examples, as with these subjects it is not possible to get satisfactory

results. Showery weather should be taken advantage of for the work. When the planting is finished, give a thorough watering to settle the soil about the roots, and a surface-dressing of well-decayed leaves or similar material is an advantage, as the soil is kept cool. Red-spider also does not get the same chance of inflicting injury, and the plants are not splashed by heavy rains beating up the soil. The after-treatment is very simple. Always keep Violets during hot, dry weather well supplied with water, keep down weeds, and a slight stirring of the soil occasionally is also beneficial. Remove runners as they appear. Against walls Violets get red-spider, and it is a mistake to suppose they will not bear sun. They stand a good deal if the soil is satisfactory, though, of course, a hot, parched, exposed place is most unsemitable. There is more than one way of increasing Violets. They are easily raised from seed, which should be sown as soon as ripe, whilst the plants may be readily divided as you suggest, getting nice tufted pieces, and if the shoots have not been taken off in the roots place them in rows in a cold frame. Any old frame will suffice, and they will succeed well. Treat them, in fact, like cuttings. Another way of increasing Violets: Early April is a good time to divide your old plants, taking care to have good soil, well dug, and, if poor, manured. Such varieties as the Single White, Double Red, Odorata rubra (double blue), Belle de Chatenay (double white), King of Violets (very rich blue), the flowers large and very fragrant, Marie Louise (too well known to need description), The Ruesian, The Czar, and Welliana, which last is very sweet, and lasts in bloom a long time.—C. T.

Grape Hyacinths.—Amongst the most charming of early spring flowers are the Grape Hyacinths, or Muscari, of which there are several kinds. The most popular is *M. botryoides*, and there are several varieties, as album (white), and pallidum (pale-blue); but some are named according to their shade of colour. This is a common and not desirable practice. *M. armeniacum* has deep-blue flowers, which appear later than the above. The Grape Hyacinths are well worth growing in the smallest garden, and where possible may be naturalised in the Grass. A row in the front of the border, or in a bed, is very pleasing, and light, sandy soil suits them best. The flowers remain in beauty also for a considerable season, displaying pretty shades of blue.—V. C.

3430.—**Annuals for show.**—All annuals that are to flower during the summer should be sown at once. If they are sown later they rush into flower quickly when dry, hot weather comes, and then they are of no use for show purposes. Sow in good ground, and as soon as the plants are 2 inches high thin them out to 9 inches apart each way. Besides those you mention the Sweet Sulden and Larkspur are two useful subjects to flower in August, and Sweet Peas are very easy to grow, and will flower at that time. If there is a stated number to be shown you had better have a few more, so as to give you a greater choice.—J. C. C.

3401.—**Sowing Grass seed.**—The mode you should follow is this: Before sowing your seed rake your lawn thoroughly, tear the ground up, then sprinkle fine earth all over very evenly. Sow your seeds and roll well. If your roller is very light roll it several times, say three times a week—lengthways and crosswise. This is to keep down worm-earths especially. When your seeds show about an inch above the ground roll once a week regularly. It will not hurt the tender young Grass. It will have a beneficial effect, and will consolidate the "seed-bed." I am sowing a tennis-ground myself in this way, and it leaves nothing to be desired. If very hot weather at a stretch comes, sprinkle with a watering-can at dusk, so that the plants and seeds may have the benefit all the night and well into the next day. Above all things, keep down the worm-earths by good rolling. Nothing will grow on or around them if allowed to remain.—S. J.

3422.—**Planting Clematises.**—It is perfectly right to water Clematises at this season on planting them out. A little old leaf-mould or manure over the roots as a mulch will also be beneficial.—E. H.

—If they were pot-plants it would not hurt to plant them out now, although if we get much frosty weather in April it will probably check their growth. Clematises if lifted from a nursery would be most suitably planted in the autumn.—A. O. BULLER.

NOTES ON DAFFODILS.

THE Daffodil is in full beauty now, and it will be useful to readers of GARDENING to make a few notes upon the flower. Everyone almost may grow the bulbs, and its culture amongst amateurs is rapidly increasing, who, as, if they will, grow as fine flowers as any that come from the nurseries or such great market places as Mr. Walter's, at Ham Common, near Richmond. The splendid blooms of Horsfield in particular seen in the market in April are grown there; but the amateur is not so well placed when exhibiting, as the larger the stock the greater chance there is of getting fine flowers. It must be a poor garden that will not grow Daffodils, no special preparation being necessary, simply a little attention to a few details. One very great point, and it applies to hardy bulbs in general, is to buy them early in the autumn. This advice may not appear reasonable now, but whilst the flowers are tossing about in the soft wind of an April day it is a time to make cultural notes. If the bulbs are planted late the chances of a very fine display are lessened, as when planted early they have a good season before them. Some amateurs delay planting as late as November; but the best time of all is early in September, when the soil is, as a rule, in excellent condition. Another error into which amateurs frequently fall is in allowing the bulbs to remain year after year in the ground without lifting. They then often refuse to flower, and complaints are rife that the Daffodils are not an easy to grow as writers assert. Several queries have recently appeared in GARDENING asking for information as to the cause of their bulbs not blooming. It must be remembered that Daffodils increase rapidly, and require lifting at least every three years, but better if two years only elapse, and it is the practice with market gardeners to lift the bulbs every year. I know of one large Daffodil nursery where the bulbs are lifted as soon as the foliage has died down, cleaned, dried, or replanted again in early autumn, the first to be treated being the charming *Poet's Narcissus*, or Pheasant's-eye, as it is familiarly called. The soil for Daffodils need be only good garden ground, such as amateurs usually possess. Of course, when the flowers are produced for market the land is well ploughed up, and in case of the hold "trumpet" kinds well manured. It is strange that, in spite of the popularity of the *Narcissus*, the list of varieties grown should be so small. I have been in many small gardens where plants are cared for and never seen the beautiful "bicolor" variety named Horsfield, for which we have to thank a Lancashire weaver named Horsfield, who was an ardent lover and raiser of flowers. Horsfield is possibly the finest of all Daffodils, the flowers true coloured, hence the description "bicolor," the broad segments or perianth of a creamy-white, and the trumpet rich self-yellow, very handsome. It grows vigorously, increases rapidly, and blooms with great freedom. *Empress* is very similar, and the flowers appear a little later, whilst they remain in full beauty over a longer season, through the greater substance of the segments, the bulbs also increasing more rapidly. Amateurs should make a note of these two fine "bicolor" trumpet Daffodils. Before March is over the yellow trumpet kinds begin to bloom, and one of the first of all is Golden Spur, a very free, robust, and striking variety, the flowers large and rich-yellow in colour. Later, but strikingly handsome, is *maximus*, which is not, unfortunately, so free-blooming as one would wish for. The flowers are very large, are of the deepest self-yellow colour, unannually rich and striking. Nor must be forgotten the *Emily Tenby* Daffodil, or *N. obvallaris*, which has flowers of a fine yellow colour, very neat and compact in shape, free, and in all respects desirable. One has only to notice this by the quantities sold in the Loudon streets in later March, and I believe that no other Daffodil is so largely grown. Countess of Annerley is a fine beautiful yellow trumpet kind, and may be mentioned amongst the best. *Paltinus* precoc is desirable for its earliness; it begins to bloom at the end of February, and there is considerable charm in the dainty pale sulphur-coloured flowers. They vary a good deal, and some of the more distinct "kinds" have received distinctive names, but this is a mistake. It is, unfortunately, rather usual to give names

to flowers that show a slight difference from things already in cultivation. As a rule, the pale-coloured Daffodils are troublesome to grow, especially that section represented by *Cernuus*, or *Cernuus pulcher*, although these are less fastidious than the majority of their kind. The soil for the bulbs should be light and thoroughly well drained. At the base of a warm, sunny wall they usually succeed well. I can give a wrinkle here as to the best way to gather Trumpet Daffodils, and that is always when the flowers are about half open, not in the bud, or when fully expanded. The half-opened buds expand well in water, and do not get sullied by the weather. It is important to notice that the Poet's Narcissus should not be so much open, and, in the case of blooms for the market, they are cut quite in the bud stage, and opened under glass, as they are much fresher and cleaner than those gathered from the open ground. These remarks apply in the case of the Irises particu-

with a distinct orange-scarlet rim to the cup, whilst the latter is white, and very sweetly scented. This reminds me how great is the variety of aspect to a collector of Narcissus. The foliage of the bold trumpet kinds is broad, and of a very beautiful glaucous colour, whilst that of the Leeds and other groups is as graceful as a Grass. The flowers often show great diversity of form, from the big Trumpet Daffodil to the Pheasant's-eye Narcissus. The only fault of such kinds as *Duchesse of Westminster* is that they are rather tender, and must be given the warmer positions in the garden. Very popular are the deliciously scented *Jonquil*, the *Camperelle*, *N. odoratus* and its variety *rugulosus*, which have rich-yellow, very fragrant flowers, and the fine old double kinds, represented by the *Sulphur Crown*, *Orange Pheox* and the beautiful double variety of the *Pheasant's-eye*, an exquisite flower, pure white, very full, and of rich fragrance. I ought

are intended simply as a guide to those who are determined to grow Daffodils, and no flower of the spring deserves to be better grown. It is pleasing when planted in clumps on the border, in colonies in the woodland, or near trees, especially if the stems rise above a tuess of Ivy. The effect of the rich-yellow flowers and deep-green leafage of the Ivy is remarkably rich. It is by such contrasts of colour that gardens, both large and small, are made more interesting. The Hoop Petticoat Daffodils are more suitable for pots, although *Citrinus* is, as far as I have grown it, the hardiest of the section, the large pale-yellow flowers being distinct and pleasing. The hulbe like a rather sheltered position and moderately light warm soil. The *Corbulariae* are charming in pots, and also the *Polyanthus Narcissus*, which are excellent for the greenhouse. I have a collection in full bloom now, the flowers ranging in colour from white to intense orange. C. T.

ROSES.

348—Roses all the year round.—To get Roses all the year round is entirely a question of good management. You certainly ought to be able to cut a few every Sunday in the year. If you keep some of your pot plants backward as possible each spring, through standing them on the north side of a wall or fence from now until October, they will make comparatively late growth, and this may be flowered well by the aid of a little protection in your cool-house. Such plants would bloom throughout November and December. Another batch should be grown on as forward as possible now, ripened off out-of-doors during August, and started steadily in November next. These will bloom in January. As to when the plants should be introduced from the cool to the warmer house, much depends upon the temperature as well as upon their stage of growth. If well ripened they will flower freely in a heat of 60 degs. to 70 degs. You have probably noticed how very full of young growth most of the Tea-scented and Noisette varieties are during late autumn, and that this is checked by the frost. If you can secure similar growth upon pot plants, and give the house protection, they will produce a batch of blooms during mid-winter.—P. U.

You appear not only to know what you want, but you evidently have some practical ideas how to obtain it, and as you have ample appliances there is no difficulty whatever in obtaining Roses all the year; but with a view to lessen expense and labour your first efforts should be directed to obtaining all the flowers you can from the open air. If you have a wall or close fence facing south you may get blooms of Tea Roses at the end of May from such varieties as *Mme. Lambert*, *Safrano*, *Marie Van Houtte*, *Mme. Falcot*, and *Isabella Sprunt*. To second these there will be the Hybrid Perpetuals, which can be had in any quantity. The next point is to secure flowers through the autumn. To accomplish this you cannot do better than have another batch of Teas in a bed or border that is fairly well sheltered. You will find some beautiful varieties amongst the following: *Grace Darling*, *Dr. Grill*, *Countess of Folkestone*, *Perle de Lyon*, *Mme. Eugene Verdier*, *Catherine Mornet*, *The Bride*, and *Lady Mary Fitzwilliam*. There are two good Bourbon Roses that are invaluable for autumn flowering. These are *Queen of Bedders* (crimson) and *Souvenir de la Malmaison* (flesh-colour); add to these the good old *Gloire de Dijon*, and you have some of the most reliable of hardy Roses. Some useful hardy early flowering Yellow Roses will be found in the Austrian Briers. The best with double flowers are *Harriouni* and *Persean Yellow*. Coming to the part of your question that refers to forcing Roses, you are probably aware that your greatest difficulty is to obtain Roses from the beginning of November to the end of February. This, however, can be done if you choose suitable varieties and have a sufficient number of plants. For this purpose the selection should be confined to the Teas, but those with very full flowers, like *Souvenir d'un Ami* and *Sombreuil* should be avoided, as they require a high temperature to get them to open. My selection would be *Lady Gales*, *Luciole*, *Mme. Charles*, *Mme. Lambert*, *Mme. Etienne Levet*,
URBANA-CHAMPAIGN

Flowers of a good type of Daffodil.

larly. The flowers should always be cut when half open. Every amateur should grow the variety of *N. poeticus* named *ornatus*. It is exceptionally free, very early, and easy to grow. Before any other kind in this particular section it should be thought of. Very charming also is *poeticus*, while *grandiflorus* is also of note. But as a rule not more than one variety is required, and that should be *ornatus*. I point out merely a few of the finest, as some 600 kinds are named. To cultivate even a small proportion of these is not necessary, and the several sections as *Barri*, *Incomparabilis*, and *Leedsii* comprise such a host of forms, differing merely in degree. The king of the *Incomparabilis* Daffodils is unquestionably *Sir Watkin*, which since its introduction a few years ago has become remarkably popular. The flowers are of very large size, the perianth broad, and the cup also, whilst the colour is a pleasing shade of yellow. Two very charming varieties are *Barri conspicuus* and *Leedsii Duchesse of Westminster*. The former of the two is a very graceful flower,

to have mentioned amongst the trumpet varieties *Emperor*, which is one of the finest of its section. Those who have sufficiently large gardens should plant in little groups or colonies the charming *N. minor*. It makes a dense carpet of flowers, small, but of a good yellow colour, in March, and for this reason should be planted freely on the rockery. I should like to see these dwarf Daffodils more grown, as they give bright colour to the border or rockery very early in spring, before Daffodils in general have commenced to bloom, and will grow in ordinary soil and position. The amateur is not wise to grow the little *N. minimus* or the very distinct *N. cyclamineus* unless he cares for Narcissus greatly, as they are not amongst the easiest to grow. *N. minimus*, so called because the flowers are of such small size, yet of exquisite shape, just like a very small edition of our common wilding, should be grown at the least in a wall, and *N. cyclamineus* likes a boggy soil. It is in its native home (Spain) found by the side of water. These few notes

Niphetos Jean Peruet, Francis Krüger, Anna Olivier, Catherine Mermet, Innocente Pirola, and Jules Fiager. If you had two each of these and divided them into two batches, you would probably get all the flowers you want during the time mentioned. If the first lot was placed in a warm-house at the beginning of October they would succeed those in the open ground. The next lot should be started gently with a little fire-heat about the end of November. With regard to the treatment of pot-plants, I would not let them flower now, but shift them at once into larger pots if they require it, and prune them slightly a month later. You had better, however, aim at getting rather large plants before you prune much. Even in your small houses the plants ought to occupy 12-inch and 11-inch pots as soon as they are large enough. Take all the plants into the open air about midsummer, and bring them under cover again at the end of September. Give weak manure-water always when the plants require root moisture.—J. C. C.

TREES AND SHRUBS.

2135.—*Garrya elliptica*.—This is an excellent hardy evergreen shrub for a south wall, but in our garden it does very well as a bush. If a good-sized plant is put out it would produce its flowers the second season. The catkins are produced on the plant which produces the male blossoms. Female blossoms are produced on a separate plant. It is a generally cultivated shrub, and very handsome when not in flower.—J. D. E.

— These are generally kept in pots by nurserymen, because they are not particularly safe to remove when once grown in the open ground. If you mean by an "established tree," one from the open ground, it is too late to move it this season; nor could a well established plant of this be moved with much prospect of success. A plant from a pot could be turned out at any time, and if a fairly strong one, you may expect to get a crop of catkins next autumn and winter.—L. U.

— As a rule nurserymen grow the plants in pots. In that case they can be planted at any time of the year. I should, however, advise the plant to be put out at once so as to give it a long season of growth. If a strong plant is procured some few catkins might be had this year, but certainly there would be next year. This plant grows very fast when the conditions are favourable—a deep root-run, fairly rich soil and abundance of water, both at the roots and over the foliage during the summer. Very often wall climbers are checked in their growth for want of sufficient moisture at the roots, as few persons seem to realise the amount of moisture that is absorbed from the soil by a brick wall. In consequence of this the plants suffer. Some care is needed in pruning the *Garrya* at any time, especially when the allotted wall space is covered. The more it is pruned the fewer catkins will be produced. It is not possible to keep this plant very neat and close to the wall and still have a full crop of flowers. A fair amount of freedom must be allowed if a quantity of flowers are expected.—S. P.

— The *Garrya* might be planted now. They are usually kept in pots at all large nurseries. There are two varieties, male and female. It would be interesting to have both, though in either case it would be impossible to say how long one would have to wait for catkins.—E. H.

3137.—**Height of *Cupressus Lawsoniana* lutea.**—Although this *Cypress* is the strongest grower of all the Golden or Variegated forms of *Conifers*, I think the one referred to in this inquiry is an exceptionally fine specimen, as I have not seen one approaching anything like the height mentioned. I planted one about twelve years ago, which grew away at once in the most satisfactory manner, but it is not near the height that is given in the enquiry. At the same time I planted all the so-called best forms of the Variegated and Golden *Conifers*, and the best I can say of them is they are disappointing, as they rarely look happy.—J. C. C.

3369.—*Araucaria imbricata*.—If the seed is fresh it is not a difficult task to raise plants from it. I have raised plants from seeds saved in England. They were planted half an inch deep in the ground in flower-pots

filled with sandy loam in the autumn. The pots were placed in a cold frame, and the soil kept moist until the plants appeared. They were left in the pots for a year, and planted out in the open ground after a year's growth. There is no difficulty at all in rearing plants. They are, of course, of very slow growth.—J. D. E.

3430.—*Passeflora Constance Elliott*.—Where too thick you can thin out some of the straggling shoots, but train in the others if you have space. When quite small I think it strengthens all *Clematises* to cut them back at the end of the season, and cover with well-decayed manure and ashes; but when plenty of strong shoots have been made, it is enough to thin out and shorten them.—A. G. Butler.

— Prune back the weak side shoots, but let all strong wood remain, laying the shoots in at equal distances apart.—E. H.

LATE PLANTING OF BULBS.

It is singular that, with all the notes appearing in *GARDENING* urging the importance of early planting of bulbs purchasers will often defer making their selection until the time the bulbs ought to be fully established and showing their flower-spikes; and when one reads of the clearance sales of bulbs in February, March, and even later, which ought to be planted in October, one cannot but think that the descriptions of "sound and plump" are rather relating to what they have been than what they really are. Any one purchasing these apparently cheap lots will find that they are by no means cheap when the quality of the flowers they produce is taken into consideration, for the very life has long since been dried out of them. Doubtless they will make a feeble attempt to bloom, but the spikes will be only a caricature of what they would have been if planted two months before Christmas, so as to get well rooted before severe weather set in. It is too late to remedy the planting of *Hyacinths*, *Tulips*, &c., but don't let the same thing happen with *Gladioli* and other late summer bulbs. Especially are *Lillies* liable to injury by excessive drying and keeping out of the soil. Plant early, for if any danger from frost occurs it is easily remedied by a covering of litter, and the bulbs are rooting and gathering fresh strength if underground, but losing their vitality every day they are unnecessarily kept out of it. If anyone is sceptical on this point, he has only to lift any bulbs left all the year in the ground, and note the early date at which they make fresh root, to convince him how unnatural the excessive drying process is. J. CROOK, Gosport.

GLADIOLI IN BEDS AND POTS.

Those cultivators of this grand autumn flower who grow the choicest kinds, mostly of the *Glandavensis* section, for exhibition, recommend that the ground should, during autumn, be deeply trenched and heavily manured for the reception of the corms or bulbs this month. They mark the selected spot of the garden into narrow beds 3 feet or 4 feet wide, with paths between. Each bulb is allowed about 1 foot of space and planted 3 inches deep. As soon as growth is observed above ground the beds are mulched with rotten manure, which is left on the surface all the summer. Tying is resorted to and liquid-manure is applied to aid development. After flowering, when the leaves begin to fade, they are taken up, left in the open for a few days to expel moisture, and are stored away with care, as many may be valued at half a guinea apiece. Bulbs of the commoner, but by no means less useful, sorts may be had, however, at a much cheaper rate, and, besides exhibiting it, there are other uses for this plant which make it invaluable in any garden. In hardy plant borders, in front of the green foliage of *Rhododendrons*, between standard *Roses* massed in beds, or in clumps at intervals near kitchen garden walks, these are positions in which *Gladioli* serve a useful and showy purpose. To grow them in the ordinary way any soil will do, but a little manure will greatly assist, and should be dug in where a clump of bulbs, say five or six, are to be planted. A handful of some approved fertiliser will answer the same purpose and is more easily applied, being scattered in the hole made at the time of planting *Brencheleyensis* (the well-known scarlet) may be bought at a 1d. per root, and mixed hybrids of *Peolons* from 10s. per 100. *Gladioli* flowers are most excellent for cutting, and when wanted in this state should be cut at an early stage and

allowed to open in water. It will be found that their beauty is not so fleeting as when left on the plant to open. In pots these are useful for conservatory decoration and also for anticipating the outdoor flowers. Plant about three of the large-flowering section in an 8-inch pot, using any ordinary potting-soil. Cover them with Cocoa-nut fibre till the sprouting growth comes through this material, then allow them to grow on in a cold pit. Feed them constantly with manure-water and never allow the soil to become dry. It is well to leave the pots plunged until flower-spikes show colour, when they will be ready to give brightness to arrangements of Ferns, Palms, and so on. The miniature *Gladioli* (*O. Colvillei albus* The Bride) is, for its distinct character, beauty, and simple culture, one of the choicest of greenhouse bulbs, so small that it is wonderful what charming spikes spring from the same. Do not delay with this sort, as the bulbs deteriorate after March. Mine are now about 3 inches above the soil; but by planting it in the pots about Christmas, as a rule it may be had in bloom if gently forced by June. From eight to ten bulbs should be placed in a 5 inch pot, and use the lightest soil obtainable. I have found to my cost it is not hardy, and requires some protection even in a cold frame during frosty weather. Yet I know of a large patch in an open garden which has been left undisturbed for several years, and goes on increasing every season. This, however, is on a slope where the soil, which is naturally of a light nature, becomes drained, therefore dry; and the bed is also protected with loose litter during winter. H.

3431.—Keeping cats out of a garden.

—If the garden is surrounded with walls or close fences, cats may be kept out, or, rather, they may be kept in when they come in, by running wire-netting along the top of the wall or fence, and bending about a foot, or rather more, of the top over at right angles. Have a few iron supports made of the right shape, and then fix the wire-netting to the iron supports. The cost would not be great; and wherever I have seen it tried it has been effectual. If the cats get in, when they tried to get back they would be balked by the bent netting.—E. H.

— The most efficient way of keeping cats out, since you object to killing them, is to put wire-netting on the top of your wall or fence and bend the top of it down away from your garden. The cats find it next to impossible to get over this; whereas upright netting, even with cat-wire along the top of it, does not keep them out, although it somewhat checks them. If your neighbours object to the wire being bent over towards their gardens, put it upright, lace cat-wire along the top and about 2 inches below, and inside the netting stretch a thin wire as tightly as possible. A cat always reaches down before jumping, and if her foot comes in contact with a thin wire she will draw it up again and retrace her steps.—A. G. BUTLER.

3371.—**Cinders and ashes**—I do not know that these are really injurious to coniferous plants, but unless the ground be stiff they are of very little use. The fine, dust-like ashes obtained from burning coke cannot possibly be of any service to *Conifers* or evergreens.—P. U.

— There would be no benefit from digging ashes in near the roots of evergreen trees, coniferous or others, though I could not say that any positive injury would be done. In porous soil ashes spread over the surface checks evaporation, and I have seen instances when so used some good has been done.—E. H.

— If you mean are cinders and ashes suitable material to plant *Conifers* and evergreens in? I say certainly not; but if not mixed with the soil, only dug in away from the shrubs, no harm will be done, of course. I do not quite understand your query, but *Conifers* require a good loamy soil, and plenty of space.—O. T.

3377.—**Treatment of Carnations.**—These are by no means difficult to grow well; the soil or position may be unobtainable. They like a nice free sandy loam best; it should be made moderately rich, only with very old manure or leaf-mould, be perfectly sweet and well compressed about the roots. None of the *Carnation* tribe do much good in a loose ground. A moderately free admixture of old mortar rubbish, burnt soil, or both, is highly beneficial. Choose an airy and sunny position, and put out the plants early in the autumn if possible.—B. O. R.

— You give very few particulars. Possibly the plant you have has a very poor habit, as it is not a very garden *Carnation* that

has such a sturdy, vigorous, and healthy growth as many of the beautiful French kinds, which I hope will soon become grown well in English gardens. Are the plants old and in proper soil and position? as upon these particulars one can alone base a correct answer. It is impossible to give proper information with so few particulars before one. If the plants are from strong layers of last year, they should be robust and vigorous. A good garden Carnation should be of strong growth, with plenty of "grass," and produce a sturdy flower-stem, bearing a free display of flowers which do not split in the calyx, and are of a fine self colour, or shades of one colour, these being the more effective; the striped show kinds, or the bizarres, and other varieties are of little value for the garden to give a rich effect.—C. T.

FERNS.

A BEAUTIFUL SILVER FERN.

GYMNOGRAMMA PULCHELLA.

This species is one of the most beautiful of all the Silver Ferns upon account of its graceful habit, the delicacy of its fronds, and the purity of its white powder. It was introduced into

coloured farinose powder, and the ends of all the pinnules are more or less crested. The cultivation of this plant is not difficult, and it is thoroughly worthy of every attention. It requires the temperature of a warm stove and a moderate supply of moisture both to its roots and in the atmosphere; but the fronds must never be sprinkled with water from the syringes, as, if this is done, the farina is washed off the lower fronds, and the whole plant becomes disfigured and unsightly. In potting drain well and use moderately-sized pots, using for soil a mixture of loam, peat, and sharp river or silver sand. In winter reduce the supply of water, but never allow the plants to become dry at the roots at any time. H.

But there are some species of Adiantum which are never moved from the stove in winter; Farleyense, for instance, will not thrive in a lower temperature. Neither is it wise to dry it off at all, though, of course, all plants, Ferns included, require less water in winter. Pterises, for the most part, will bear a lot of hardships, especially as regards temperature; but they should never be dried or rested, in the usual sense of the term. The same remarks, in a less degree, apply to Maiden-hairs, the common Maiden-hair, Adiantum cuneatum, is sometimes dried off and then cut down just before starting; but the treatment is not natural, and if carried out with other Adiantums injury would result.—E. H.

— The temperature of nearly all plant-houses is, of course, lower in the winter than during the summer, so that even if kept in the same house they will be subjected to a lower range, and this is right and natural. At the same time very few of the varieties of either Pteris or Adiantum are truly deciduous, and I think they never look so well or grow so luxuriantly as when kept slowly moving in a generally warm and moist atmosphere at all, or nearly all, seasons. The temperatures of a cool fernery should never fall below 45 degs., and generally range from 50 to 60 or 65 degs. during the winter, and 10 or 15 degs. more in the summer time.—B. C. R.

— It is impossible to say why the young fronds of the Ferns turn brown without some particulars as to the treatment, &c. The atmosphere of the house may be too dry, or there may be too much steam from the pipes when syringing. What are the pipes painted with (if anything)? Fuchsias, Camellias, Calceolarias (herbaceous and shrubby), Chinese and other Primroses, Hsbrothamuses, Spiraeas, Celsia cretica, and Lapagerias will be most likely to succeed, but during the height of the summer you will find ordinary "Geraniums," Begonias, and others bloom freshly enough in a shady house.—B. C. R.

3428.—**Asparagus Ferne.**—The quickest way of working up a stock is to sow seeds, but it is not always possible to obtain good seeds; and then the next best course is to carefully divide the plants, partially shaking them out, so as to work in a sharp knife to separate the crowns. The young plants should be brought on in a warm, close house or pit till well established. Afterwards place in warm greenhouse. They make splendid room plants.—E. H.

— The plant alluded to is Asparagus plumosus, an elegant evergreen climbing plant from South Africa. It is an error to call it a Fern; it is not a Fern in any sense of the word. It requires hot-house treatment; but the plants would do well in the greenhouse in summer for a time after it has made its growth. The plants are propagated by dividing the crowns and planting them out separately in flower-pots. There is a dwarf variety, A. plumosus nanus, which is the best form.—J. D. E.

— I presume that by this term Asparagus plumosus (which is properly not a Fern at all) is meant. This elegant and useful plant thrives best in the temperature of a mild stove, a range of 60 to 75 or 80 degs. being very suitable. Seedlings make much the best plants; but as it is only old, large, and well-established plants that produce seed it may be some years before your plants will do so, even under generous treatment. Cuttings of the shoots, using short, starchy pieces or side-growths, may be struck in sand in a warm, close, moist, and shaded frame in the spring, or the old roots may be divided, and increase obtained in this way.—B. C. R.

3442.—Ferns, &c., in a greenhouse.

—The fronds of Maiden-hair Ferns are likely to become brown in a greenhouse, because they are really hot-house plants, and do not like the dry, cold air of an ordinary greenhouse. They will do in the greenhouse in summer when growth has been made, but should not be placed in a draught, for the tender fronds cannot endure it. One of the best plants for such a greenhouse is the Lapageria alba and rosea. Fuchsias, Pelargoniums, and Camellias are excellent plants, especially the Camellia. Geraniums (fragrant) is an excellent plant; and the sweetly-perfumed Daphne indica would be a charming piece of spring-flowering.—J. D. E.

Gymnogramma pulchella.

this country from Venezuela by M. Linden, of Brussels, about the year 1855. The fronds are supported upon a dark chestnut-brown coloured powdery stem some 9 inches long. They are triangular in outline, and upon well-grown specimens attain a height of about 18 inches, and from 6 inches to 9 inches in breadth. The segments are very finely divided, as will be seen by the annexed illustration, which has been taken from a portion of a frond some 2 inches long. The upper side of the frond is of a bright, lovely green colour; beneath it is covered with a dense, silvery-white farinose powder. G. pulchella has not produced many varieties. Occasionally a form appears amongst a batch of seedlings in which some of the segments are golden beneath instead of white, and in the variety Wettenthaliana the under sides of the fronds are densely covered with a sulphur-

3429.—**Treatment of Ferns.**—The common forms of Pteris and Adiantum, being cool-house Ferns, naturally should be grown in a cool conservatory or greenhouse, in which the night temperature in the winter would fall to from 45 degs. to 50 degs.; at this season, owing to the cooler temperature, growth would not proceed rapidly as in the summer, but would not cease altogether. Is this what you mean by their being at rest? The general idea of rest in a plant is that the foliage ceases to grow, turns brown, and dies off; but there is no advantage in disfiguring your house by compelling bardy Ferns to rest.—A. G. BUTLER.

— Ferns when at rest and kept dry may do in a lower temperature than they usually occupy; but there is nothing gained by keeping them in a lower temperature than 40 degs. at night, and many growers never let them fall below 50 degs.

ORCHIDS.

NATIVE ORCHIDS.

I AM asked by one, "Harry Windsor," what native Orchids are to be found in the neighbourhood of Duncester, and how to treat them? Well, now this is a part of Yorkshire that I have never been in, and, therefore, I am unacquainted with the soil of the neighbourhood, and it will not do to even guess at what he will find; but I advise him to search well, and to never go out for a country ramble without being armed with a trowel and a close tin-box. These plants are not likely to form such stout tubers, after the removal, for the first year, and very little flower must be expected the year after their planting in your border, and I should advise "H. W." to get some of the rarer kinds from Messrs. Backhouse, of York. Some few years ago, I had a lot of native Orchids in my garden near London, and a portion of it was devoted entirely to them, and was made up with soil to suit each particular kind, because those found

Orchises: but one can now scarcely find a single specimen in a day's hunt for them. So do not set about your hobby in a too avaricious manner. The following eighteen genera include all the kinds of British Orchis, some of which you cannot obtain in your neighbourhood, because they are very local in their distribution, beside being rare: *Aceras anthropophora* (Green Man Orchis), chalky soil and loam; *Cephalanthera*, chalky loam and sand; *C. ensifolia* (Sword-leaved Helleborine); *C. grandiflora* (White Helleborine); *C. rubra* (Red Helleborine); *Corallorhiza* (Coral-root), leaf-mould and peat, rare and local; *C. innata* (Coral-rooted Tway-blade). *Cypripedium* (Lady's Slipper)—see illustration; this used to be in your county, but is now extinct; chalky loam and sand. *C. calceolus* (Yellow Lady's Slipper); *Epipogon Gmelini*, very rare and local; *Epipactis* (Helleborine), leaf-mould, peat, and sand; *E. latifolia* (Common Helleborine); *E. purpurata* (Purple Helleborine); *E. palustris* (Marsh Helleborine); *E. rubiginosa* (Rusty Helleborine); *E. viridens* (Green Helleborine);

(Lady's-Tresser), leaf-mould and peat; *S. festalis*; *S. autumnalis*, very fragrant; *S. gimmpara*, very rare and local. I think these comprise the whole of the species of our native Orchids, but some few species might be found from amongst the North American and other cool country Orchids, which may be made available to make the border more showy.

MATT. BRAMBLE.

THE PELICAN-FLOWER (CYPRIPEDIMUM IRAPEANUM).

THIS flower is one of the Mexican beauties belonging to the deciduous terrestrial section. I am asked by "B. B. B." where it may be obtained and how to grow it? Well, now I must say that this is a species which I have never flowered, but I see no reason why it should not thrive well if properly potted in good brown, somewhat spongy peat and Sphagnum Moss, well mixed together, and grown in the temperature of the cool Cattleya-house. This plant is found in Mexico at an elevation of between 3,000 feet and 4,000 feet, and therefore it requires a slightly warmer place than the *Odontoglossums*; but although I had some very fair-sized clumps of this plant I have never had it in flower. It grew well enough, and the shoots duly ripened off and died away; but there was something in the rooting, I think, that did not agree with the species, or it should have been blessed with some of its rich bright yellow blooms, and I likewise should have been able to satisfy my enquirer and to tell him how to bloom it. The name of Pelican-flower is not given it from its colour, for this is of a rich bright golden-yellow, but from its large column, which is bent over and resembles somewhat a pelican or some bird plucking its breast and stripping itself of feathers. This plant has no companion to grow along with it, for *C. spectabile* and *C. pubescens*, together with several other kinds, are temperate, if not hardy, species, and so this plant stands by itself as a deciduous kind, requiring a warm-house. I do not know if this plant is capable of causing anything like the results stated by some writers to have been inflicted on them by several of these terrestrial species from North America; but I have worked amongst many hundreds of them and *C. Irapeanum*, and never felt the least tinge of poisoning; but a man that had worked amongst plants of this Mexican species appeared to be somewhat affected. His skin appeared to be suffering from some cause of irritation, but my own was quite unaffected. In answer to my friend's enquiries of where he can obtain this plant, I think I have seen Mr. Sander have some large pieces of it, and a few years ago I saw it in quantity in the Messrs. Backhouse's establishment at York; but whether either firm is now in possession of it I am unable to say, but, if not, someone should instruct their travellers to send this plant home, and now *Cypripediums* being so much in favour, there should be a brisk demand for it, and who knows but we may find it produce a pure-white form?

MATT. BRAMBLE.

Lady's Slipper (*Cypripedium*).

growing in chalky soils will only live in a similar mixture; others, again, thrive best in leaf-mould and peat, whilst others require loam and peat, and some sharp sand may be applied to all the beds. Take care that the border is properly drained, for although some few kinds do grow naturally in marshy places, it is very seldom these can be imitated successfully in an artificial state, and such kinds must receive a greater amount of water to their roots. The border should be sown with some dwarf ornamental Grasses, larger kinds being set out singly at intervals, and a few annual seeds should also be dropped in here and there; but the Orchis should always be left clear from these plants. I cannot point out any feature so that you may be able to distinguish them by; but if you have no knowledge of these plants, get acquainted with someone in your neighbourhood who has, and get a few practical lessons from him. One word, however, of caution—do not ply your trowel too freely, so as to exterminate these pretty and interesting plants, for I know some places, especially in the south, which used to be famous for the Bee and Spider

Goolyera, leaf-mould and sand, local and rare; *G. repens*; *Gymnadenia* (Fragrant Orchis), chalky loam; *G. conopsea* (Red-handed Orchis); *Habenaria*, leaf-mould, peat, and sand; *H. albida*, very fragrant; *H. bifida* (Butterfly Orchis); *H. viridis* (Frog Orchis); *Herminium* (Musk Orchis), chalky loam; *H. monorchis*, odour of Musk; *Liparis* (Fen Orchis), leaf-mould and peat; *L. Loeselii*; *Lileta*, leaf-mould and peat; *L. cordata* (Lesser Tway-blade); *L. ovata* (Tway-blade); *Malaxis* (Bog Orchis), leaf-mould and peat; *M. pallidosa* (Marsh Tway-blade); *Neottia* (Bird's-nest Orchis), rare and local; *N. Nidus-avis*; *Neottinia* (Small Moth Orchis), rare and local, chalky loam; *N. intacta*; *Ophrys*, chalky loam; *O. apifera* (Bee Orchis); *O. aranifera* (Spider Orchis); *O. nuceifera* (Fly Orchis); *Orchis*, chalky loam; *O. hircina* (Lizard Orchis), very rare and local; *S. rutifolia* (Marsh Orchis); *O. laxiflora* (Loose-flowered Orchis); *O. mascula* (Purple Orchis); *O. maculata* (Spotted Orchis); *O. Moris* (Green-winged Orchis); *O. militaris* (Man Orchis); *O. pyramidalis* (Late-flowering Pyramidal Orchis); *O. ustulata* (Dwarf Orchis); *Spiranthes*

2438.—*Nerine carnifera*.—This is the well-known Guernsey Lily, and may be purchased in the seed shops when the flower-scapes are showing, the bulbs having been kept quite dry for some time previously. Grow them in flower-pots very freely over a dung-bed, with a gentle bottom-heat, in a garden frame. They need a good season of growth, and when the leaves decay keep them quite dry at the roots. They need not be repotted every year.—J. D. E.

— Do you take care of the leaves when they do come up by giving them a warm greenhouse all the winter, with moderate supplies of root-moisture, and guard them from being injured or kept in a dark position? If you do this the bulbs ought to flower every autumn. During the summer they should have no water, and the pot stood on a shelf in the greenhouse, fully exposed to the sun. If they are potted in fresh soil once in two years, that is often enough, and the proper time to do so is in August, or directly after they have gone out of flower.—J. C. C.

2659.—Weeds.—It would be better to get some good weed detector, or a sprinkling of salt applied on a damp day will assist you. There are many good articles advertised, but always take care not to let the material touch the Grass edge.—C. T.

FREESIAS.

THESE beautiful flowers are deservedly becoming very popular, for not only are the flowers beautiful, but the perfume is exquisite, a strong yet pleasant smell, entirely different to Hyacinths, Narcissus, or many other bulbous plants that prove too odorous for indoor decoration. Their culture is very easy, although many fail with them, and as they are eminently suited to the wants of amateur cultivators I will briefly describe my method of growing them, in the hope that many will try again and succeed. Procure good bulbs early in the autumn or rather late in the summer, and pot them at once. I use 5-inch and 6-inch pots as being the most serviceable, and the soil I find best is turf that has been cut and stacked up one year; this is broken up fine, and a little leaf-mould and rough sand or road-grit mixed with it, the pots are drained in the usual way, and about a dozen bulbs are placed in a 6-inch pot, covering with about 1 inch of the finest soil. No water is needed for some time, for if the compost is moderately moist at potting time, and the pots are set on the floor of a cold frame, they will need no water until the tops are visible above ground and the roots are active below. A cold frame suits them well until the middle of October, when they will be growing freely, and should be neatly tied up and transferred to a shelf near the glass in any house where an intermediate temperature is maintained, and if kept free from fly, and carefully watered with water, using a little liquid-manure to strengthen the flower-spikes, they will produce finely-branched spikes of flower that will amply repay you all your trouble.

J. GROOM, Gosport.

PROPAGATING TUBEROUS BEGONIAS.

SEVERAL queries have recently appeared in GARDENING respecting the propagation of Tuberous Begonias, and it may be, therefore, interesting to your readers to know the method followed by Mr. John Laing, who has largely helped to bring the flower to its present perfection. Tuberous Begonias may be propagated in four different ways—by seeds, cuttings, division of the tubers, and leaf-cuttings. The two best methods, advises Mr. Laing, are by seeds and cuttings. Increase by cuttings is only essential in the case of choice standard kinds to be preserved true to name. Those are mostly used for pot culture, and are the most improved or advanced types of the race from whence the finest seeds are derived. Young shoots from near the base of the plants make the best cuttings, and may be inserted any time during the growing season, but the earlier they will root and form tubers. A few of the young growths that arise from the tubers in spring may be taken; but the fact must not be overlooked that to take the same libortice with them as with Dahlias would be ruinous to a good display of bloom on the old plants for a season. The cuttings should be inserted singly against the side of thomb-pots in a compost consisting of loam, leaf-soil, and sand in about equal proportions, and plugged in Cocoa-nut-fibre in the bed of a propagating-pit or frame, and shaded till they have emitted roots, and may be grown on if required for late blooming. The young plants should be kept in the cutting-pots till the following spring, and this is the more essential in the case of late-arrived cuttings, but where practicable the latter should be potted and kept growing. Propagation by seeds is at once the most legitimate, speedy, profitable, and certain mode of increasing this class of Begonias, either for pot culture or bedding out. There will be always a certain amount of speculation with regard to the colour, habit, and character of the seedlings the first year, but if derived from a good strain, they seldom fail to give satisfaction, and may be assorted for future work as they come into bloom. The seed may be sown at almost any time of the year, according to the convenience and requirements of an establishment, but the third or fourth week in January is the most suitable. Those who have a sufficient command of fire-heat will find it advantageous to sow early in the year, as the seedlings are liable to damp off than when they are germinated in May, June, or July. The seeds should be sown in square, round, or oblong pans, or shallow wooden

boxes, in a compost of light, porous material, consisting of flaky leaf-soil, a little loam, and plenty of sharp sand. This must be mixed, and used to a rough state, with some finely-sifted material on the top to form a smooth and level seed-bed, which should be pressed firm, watered, or, better still, dipped, and then the tiny seeds carefully sown. Place the pans or boxes to a temperature of 65 degs. to 70 degs., with more bottom-heat. Prick out the seedlings into other boxes from time to time as soon as they can be handled with a finely-pointed piece of wood, divided at the point to lift the seedlings. When they begin to get crowded transplant them into other boxes at a greater distance apart. By the middle of May they are ready for hardening off, and during the first weeks of June may be planted out. Manure the ground well for the plants in the autumn, and expose the soil to the action of the frost by digging it up roughly. Old tubers intended for bedding-out should be started about the last week in March or the beginning of April, and small-sized pots will be quite sufficient for them. Begonias always succeed best when the weather is warm and showery in June, and rather drier in July and August. C. T.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editors of GARDENING, 37, Southview-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to do with the present time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

- 3453.—Moss on a lawn.—My lawn has become covered with Moss. Will someone tell me the best thing to do to get rid of it, also the cause of it?—C. MacGILL.
- 3457.—Raising Trilliums.—Wanted to know the best way of raising Trilliums, and how to grow them? I have no glass beyond a cold frame.—M. L. P. F., Norfolk.
- 3458.—Making a hot-bed.—Will anyone kindly tell me the best way to make a hot-bed? I am growing some Melons, and should be glad of any suggestions on this point?—H. C.
- 3459.—Cocoa-nut Palm.—I have had specimen of above brought me from Jamaica. How to be treated? Must it be put in soil or otherwise, and how is it best nourished?—SIOGA.
- 3460.—Plant "Aloeka Bride."—I have some seeds called "Aloeka Bride." Will someone kindly give me the botanical name of the same and cultural directions?—M. L. P. F., Norfolk.
- 3461.—Lily of the Nile for market.—Will anyone kindly inform me about procuring and growing for market Lily of the Nile to have bloom from December to March?—JOHN DAVENALE.
- 3462.—Larch decaying.—Will anyone kindly say if there is an antiseptic application for home-grown Larch timber with its bark on, which may serve to retard decay?—R. L. A., Woodlands, Bamber.
- 3463.—Time for planting bulbs.—Will someone kindly tell me when bulbs, such as fly-catchers and Narciss, should be planted in the open ground to ensure flowering next spring?—NIL. DEUBERANDP.
- 3464.—Plants for a span-roofed greenhouse.—I have just put up a 12 feet by 8 feet span-roofed greenhouse, heated with a two pipe (hot and return) "Inchcliffe" stove. What plants at this time of year should I start in it?—AMATEUR, Scotland.
- 3465.—Culture of Arum Lily (Callie athiopica).—I should feel much obliged if someone will give me information respecting the culture of this plant, how to get it to flower, and whether it must be kept in a warm place and well watered?—K. LEASER.
- 3466.—Seedling Cyclamen.—I have some strong young seedlings potted off they were sown in autumn. Will someone kindly tell me when they ought to flower, and how I ought to treat them during the summer months? I have a greenhouse.—GARDENING.
- 3467.—Plants for a shaded plot.—Will someone kindly mention what could be planted on a shaded plot, and which gets a little morning sun? The plot is a large oval one, a small round plot in the centre, and the outer circle divided into four, with walks between. The three inner do very well with "Geranium" and "Calepaul" (I think) and the south is lying towards trees, which shade it very much, and "Geraniums" grow to nothing but leaves.—ENQUIRER.
- 3468.—Treatment of Balsams.—Will someone kindly inform me how I ought to treat Balsams? I have a lot of seedlings, and want information about watering, &c. They are now in a hot-bed. When ought they to be put in the greenhouse?—GARDENING.
- 3469.—Anemone fulgens.—I have some of these planted in April last year are not up yet, with the exception of one or two; what can be done to make them flower early in spring? Can they be taken up now before flowering, and dried off and planted again in autumn?—DONOAL.
- 3470.—Cytisus racemosus from seeds.—I would like to know how to grow Cytisus racemosus from seeds? I have a glass-house, temperature kept at about 60 degs. minimum, hot and cold frames each side, also a separately built conservatory, temperature about 60 degs.—QUESTANT.
- 3471.—Violets in winter.—I shall be obliged if someone will tell me how many plants of Double Violets (sweet-scented) would be necessary to furnish button-holes for two during winter months, and what kinds are most to be depended on? I have only garden frames in which to winter them.—K. W.
- 3472.—Flowers for winter, &c.—What flowers may I expect the gardener to give me during the winter months? I have plenty of hot-houses and a stove, but very few flowers to show for them. I require flowers that will travel and last well for sending to friends and hospitals.—MOTIV.
- 3473.—Artificial manures.—Could guano or some other artificial manure be successfully used as a substitute for ordinary manure for an herbaceous border, and which would be the best time for using it? Having Narcissus in the border, I am anxious to avoid the use of stable-manure, as it causes the bulbs to decay.—Z.
- 3474.—Cutting down Delphiniums, &c.—I shall be glad to know if it does harm to cut down to within about 8 inches of the ground after they have done flowering plants of Delphiniums and Lupinus polyphyllus? I have these growing in a large herbaceous bed, and they shade the later flowering plants.—SUTTON.
- 3475.—A plague of ants.—I am very much troubled with ants in my garden. I have three Peaches on a west wall now in bloom; but when the sun shines on them they are swarmed with ants. Will they do much harm, and I should be obliged if someone would kindly inform me of the means for their destruction?—GEORGE.
- 3476.—A furnace for a flue.—"A" B. C. R." advises me to have a deep square furnace for my flue. I should feel obliged if he will give me full directions for building one for a house 14 feet long; also how he regulates his fire in same, as I find by having a damper in chimney the sulphurous fumes get into the house?—TORRIS.
- 3477.—Border Carnations.—Should border Carnations be watered during this very dry month, or, although they have not yet begun to grow, they look inclined to wither, the ground being so parched from the heat of the sun? As the nights are cold, I am afraid the plants may suffer if watered, so cannot tell what treatment is best?—M. S.
- 3478.—Orchid-leaves turning yellow.—I should like to know the reason of my Orchid having their leaves yellow? I have only a few months put them in the greenhouse, the temperature of which is at a mean 60 degs. The Dendrobis and Lycastes are not so bad, but the Cattleya Trianae and Cypripedium are turning yellow, albeit the former are flowering.—QUESTANT.
- 3479.—Lily of the Valley.—Will "J. C. C." or some other reader kindly answer the following query as to the treatment of the Lily of the Valley outside? I put on a mulching of rotten manure 4 inches thick last November. Should the lily be hard to the roots to make them flower, or should the manure be laid on to form a nourishment to the roots through the summer months? Soil, light sandy; aspect of bed, north-east.—A. E. J.
- 3480.—Worms in a lawn.—Last spring I had a small piece of ground, including a path, dug and turfed. Toward the latter end of the summer I noticed the Grass seemed to be dying away, and it has now disappeared altogether. There are a number of small holes all over the ground, which must be made by worms, as they cast up the earth through these holes. Will someone please tell me how I can kill these pests to enable me to have fresh Grass for this year?—PANTS.
- 3481.—Treatment of Crown Imperiale.—Will someone kindly tell me how I should treat Crown Imperiale to induce them to flower? With me they are in the ground for some years without being disturbed. In a clump of twelve spikes there are only two with bloom, and those not a grand circle of flowers as I have seen elsewhere, but only three or four miserable blooms. They are in a mixed border, well dressed. The soil is rather heavy.—ENQUIRER, Devon.
- 3482.—A high hedge.—I wish to form a high hedge from 8 feet to 12 feet as a screen round one side of a garden. Will anyone advise me how I can do most quickly and effectually? I should prefer it to be evergreen, if such a hedge can be grown in a few years. Is Cupressus Lawsoniana suitable for the purpose? Will it stand clipping, or does it or any other species of Holly, Yew, or Privet? How long would it be before a screen 5 feet high? What are the relative merits of Holly, Yew, Laurel, and Privet? Would Querc or Cherry Plum (Myrica) form a screen as required?—O. P. E.
- 3483.—Treatment of Fuchsia.—I have the following Fuchsia—viz., Mr. F. Gies, Moleworth, Coachman, Lamsaline, Monstrosa, Phenomenal, Rose of Castile, Mrs. Gibson, Avalanche, Jules Chretien, Deutsche Kaiser, Mr. Marshall, and several others both double and single unnamed. I shall be much obliged for any hints as to special treatment and habit of growth of any of the above, and also as to treatment of Fuchsia in general, as last year with me many dropped their buds just as about to open, or does it or any other species of Fuchsia really deteriorate? My old plants are growing well now and have been repotted in 6-inch and 8-inch pots; the young plants are in 4-inch house-lining pots, and top-dressed, covered with a Vine. Last year I had the plants with alternate weak sections of Clay's Fertiliser and Rabbit manure; perhaps this was

3468.—Treatment of Balsams.—Will someone kindly inform me how I ought to treat Balsams? I have a lot of seedlings, and want information about watering, &c. They are now in a hot-bed. When ought they to be put in the greenhouse?—GARDENING.

3469.—Anemone fulgens.—I have some of these planted in April last year are not up yet, with the exception of one or two; what can be done to make them flower early in spring? Can they be taken up now before flowering, and dried off and planted again in autumn?—DONOAL.

CHRYSANTHEMUMS.

CULTURE OF DWARF CHRYSANTHEMUMS.

MANY amateurs with limited convenience are compelled to dispense with many varieties in both the Japanese and Incurved sections on account of the objectionable height they grow when treated by what is known as the ordinary method for producing large blooms—viz., allowing them to grow uninterruptedly until the first natural break is made, when three additional shoots are taken up, removing all others. The height some varieties will grow under this method of culture entirely renders them useless to the amateur with his limited space. By following a system of "cutting down" the plants, which I will describe, he may grow many more varieties than he otherwise could, as the height is much reduced, and really good blooms can be had also. But I would warn the cultivator of "cut-down" plants that he must not expect blooms of the same quality as can be had from plants grown by the ordinary method. The "cutting-down" plant, however, renders them dwarf and more suitable for decorative purposes, especially in preparing groups for conservatories or exhibition. Plants of naturally dwarf-growing sorts, as *Avalanche*, *Mrs. Falconer Jameson*, *J. Staubersugh Dibbens*, and *Middle*. *Maria Hoste* can be secured carrying really good blooms, and not more than 2 feet high from the top of the pot, and other sorts in proportion. Now is a good time to make

A SELECTION OF VARIETIES suitable for the plants struck in December or January ostensibly for the production of large blooms. Nearly every cultivator strikes more cuttings than he actually requires. Such as these can be set aside for the growth herein described. Do not top the plants, but train them with one stem. As they are mainly used for grouping, and as they are generally stood close together when in bloom, 9-inch pots will be large enough for the final shift. If possible, the pots should be of one uniform size; therefore, after the cuttings are struck place them in 3½-inch pots and then into these 5½ inches in diameter, using for this shift a compost of two parts loam, one part horse-mannure or leaf-mould. To every bushel of the compost add 2 lb. bone-meal or Thomson's Vim-manure. If the loam is heavy add sharp silver sand and charcoal to render it thoroughly porous. The plants require a large supply of water. The roots should be in a condition to receive it easily, which is not so when the compost is of a close, retentive character. Chrysanthemums revel in much moisture at the root, but the condition of the roots should be rendered sweet. Stagnation about them results in a loss of the lower leaves, disfiguring the plants, rendering them totally unfit for decorative groups. For the final potted add one more part of loam and 1 lb. more bone-meal.

THE SOIL ought to be used in a rough state, and be pressed firmly into the pots. Chrysanthemums delight in soil that is firm, and much better results than ensue. The growth made is short-jointed, firm, and luxuriantly developed.

flabby blooms. The roots ramble away far too quickly in loose soil and are less fibrous. They entwine themselves around the sides of the pot, leaving the whole of the inside of the ball practically rootless. Plants growing under these conditions require more artificial food, as the roots do not appropriate so well what is contained in the soil. When the 3½-inch pots are full of roots no time should be lost in transferring the plants to larger pots. It is while they are growing to the second-sized pots that "cutting down" takes place. Those varieties that naturally flower late, of which the *Princess Teck* family among the Incurved, *Boule d'Or*, *Florance Davis*, *J. S. Dibbens*, *Etoile de Lyon*, and *W. W. Coles* of the Japanese section are representatives, should be cut down first, commencing about the 20th of May. Mildew-proof varieties like *Jeune d'Artois*, *Princess of Wales*, and the "Queen" family, *Avalanche*, *Mlle. W. Hoste*, *Mons. Berard*, and *Vivand Morel*, about the first of June, and the early flowering sorts such as *Edwin Molyneux*, *W. H. Lincoln*, *Gloire du Rocher*, *Lady Selborne*, *Sunflower*, and *Middle*. *Lacrole* about the middle of June. I give these few names as a guide to cultivators in making a selection; many more might be given, but would occupy too much space; sufficient have been named to guide the cultivator in the treatment of those sorts known to each. It is well to take into consideration the purpose for which the plants are required in determining the height at which they are to be cut.

DWARF-BLOWING varieties like *Avalanche* and *Vivand Morel* are best suited for front rows of groups. These may be cut down to within 4 inches of the soil, the others to 6, 8, and 12 inches, selecting the varieties accordingly. *Fair Maid of Guernsey*, *Mme. C. Audignier*, and *Mrs. J. Wright* would come under the last-named height. As the new shoots are not so freely made from the old wood as from the young plants of small-flowered varieties like *Mrs. G. Rundle* or *Elaine*, which are intended to have more branches each, should not be cut so low as the larger-flowered varieties. Before cutting, it is well to determine how many blooms the plants are intended to carry as a guide in cutting down. The large sorts, like *Sunflower*, *Etoile de Lyon*, and the *Queen of England* family in the incurved section exceed the best when three only are allowed, or at the most four, shoots to each, one shoot carrying one bloom. Varieties like *Elaine*, *Lady Selborne*, or the *Rundle* family may have from four to six branches. Whatever quantity is decided to allow to each, the cultivator must bear in mind that the more blooms on each plant the smaller they will be individually. If the finest flowers are wished for, three is a fair number to leave upon each plant.

GREAT CARE must be exercised in watering the plants after they are cut down. They do not require much water at the roots for some time. If they can have the protection of a cold frame so much the better, as they can then be protected from showery weather. Syringe the plants twice daily during bright and dry weather to assist the shoots starting, and if the sun be very hot at this time a little shade in the middle of the

day can be applied. As soon as the shoots are long enough to determine if they are perfect, dish up the number required. At this stage transfer the plants to their flowering-pots, and when rooting into the new soil remove them to their summer quarters, which should be in an open situation to the south, but protected from easterly winds and also those blowing from the south-west. Allow them ample space, as crowding quickly spoils their appearance, drawing them up weakly and ruining the foliage. Tie each branch to a stake separately to prevent their being broken or the leaves damaged by chafing during gales of wind, and as soon as the pots are full of roots stimulants may be supplied. The first buds produced on the shoots after cutting down should in nearly all cases be selected as best suited for producing large blooms. They will appear from the first to the end of August, and it will be soon enough if some sorts show their buds the first week in September, say such as the *Queen* family. Sometimes a bud on plants of this latter section will show during the first week in August. This is too early. In this case run it out and wait until the next one shows, which will be about the middle of September. When the buds on the late flowering Japanese sorts show even as early as the end of July they should not be destroyed. When the

BUDS ARE SELECTED, take off all growth shoots, which are freely produced at this stage. Commence housing the plants at the end of September, beginning with those that are backward as a means of hastening them on. Place them as near to the glass as possible in a cool-house, admitting abundance of air to keep the growth as stocky as possible. Where this is neglected the peduncles run out to an indeterminate length away from the foliage, which detracts from the appearance of the plants. Be particular that insect pests of any kind do not obtain a firm hold on the plants before the usual remedies are applied. E. M.

3456.—**MOSS ON A LAWN.**—Have the lawn mown with a scythe, and tell the man to pare it down close to the surface. If this is done in dry, hot weather the sun will soon bake up the roots of the Moss, but the Grass, being deeper rooted, will survive. If the lawn is much shaded the above plan is of no use. In that case get a fine-toothed iron rake, and scratch out the Moss by working the rake to and fro. In either case give the lawn a dressing of rich soil or rotten manure in the autumn to stimulate the roots of the Grass.—J. C. C.

3471.—**VIOLETS FOR WINTER.**—A good deal will, of course, depend on the size of the plants in the autumn, as to the number that would be required, and also how many times a week they would be wanted. Thirty-six plants of *Double Blue* (*Marie Lonsie*), and the same number of *Double White* (*Swanley White*), would not be too many, and even these will not give you any flowers in very cold weather during the winter. At the same time the numbers I have mentioned will produce all the blooms you want in a fairly good season. Garden frames will do very well to winter the plants in, but they should have a thick lining of coal-ashes around outside.—J. C. C.

GARDEN WORK.

Conservatory.

Flies must be kept free from green-fly; they congregate if left undisturbed in the centre of the flower-stems, and often do injury to the blossom-buds. When a plant gets thoroughly infested they are difficult to destroy, hence the best course is to tackle the first fly, or even be in front of it with preventive measures. There are plenty of insecticides now, both for dipping, syringing, fumigating, and to use in the form of dry powder. Watering has been rather a heavy business lately, especially where shade has not been used. Without shade blossoms soon wither; unless there is a breeze with a north wind, the removal of such things as Asaleas, to the season of bloom will be a short one. There is no doubt that for shading purposes canvas blinds are best, but they are expensive, though not so much so, I think, as formerly, and to the case of houses insufficiently heated the blinds will be useful during sharp weather in winter. This is a good season for rearranging hanging-baskets. Ivy-leaved Pelargoniums should play a prominent part in this work, the growth is so suitable, and the blossoms of the best varieties are very effective. Large baskets may be placed now with sobriety. These are best started in a warm house to be brought to the conservatory later on when coming into blossom. Tropaeolum, Lophospermum scandens, and Thunbergia alata do very well for draping large baskets. A large wire-basket draped with Lophospermum scandens, and filled above with Fuchsia Rose of Castille will last all the season. Sedum carneum variegatum will form pretty drapery for a smaller basket furnished with bright-coloured Begonia. Zonal Pelargonium for winter blooming should be shifted into larger pots as required. Specimens now in course of training may have liquid-manure as soon as the pots are well filled with roots, but not before. Pelargoniums of the old-fashioned show type are very gay just now, and if well supplied with water, liquid-manure being given at intervals of two or three days, will be useful for some time. We need to make a greater use of these years ago. I have had specimen Pelargoniums plunged out to a cold ash-bed to keep back for late blooming, but in these days we had not the many beautiful Zonals in such variety as at present; but we had our compensations, not the least of which were the sweet-scented "Geraniums," which were often growing into large bushes. I often wish we had more of these old-fashioned "Geraniums" now. Growing plants of all kinds should be kept in condition by nipping off the points of the strong shoots which are growing away, and which, if left unbroken, will destroy the perfect symmetry of the plant. All necessary repotting and the shifting on of young stock must have prompt attention. Climbers on the roof should be looked over once a week.

Stove.

Droserae and Crotons have put on colour during the late bright weather where not heavily shaded, in fact, I think it is a mistake to shade anything heavily; the thinner the shade the better, and even a thin shade need not remain long over foliage plants which require solar light to bring out the bright tints. Cuttings of Crotons will root freely now in a bed of Cocca-nut fibre over a tank of hot-water, such as is common in propagating houses. The small-folaged Crotons of the angustifolia type are graceful table plants in a small state. Take off and start in single pots suckers of the Screw Pine (Pandanus V. litchi), which is, I think, the best kind to grow. Caladiums in small pots will root now into large plants if shifted on into larger pots and given plenty of heat and sunshine. Tabernaemontana Canasana is a useful flowering stove-plant, which may be grown with the Gardenias in a mixed collection of stove-plants. Gardenias are so difficult to keep free from mealy-bug, that unless time enough can be given up to keep them clean, it is, perhaps, hardly worth while attempting their culture. In a small collection of stove-plants they are rarely done well, chiefly because the temperature kept up is too low, otherwise they are neither difficult to propagate or grow. If the Gesneriae are not yet started no time should be lost in getting them on the way; they must have heat, moisture, and shade. For winter-flowering work up a stock of Hebeclidium laetumum. Continue to put in cuttings of Poinsettias.

Ferns under Glass.

These are now getting into good condition, and must have more room in the fronds are to be properly developed. Two Ferns, most of which fortunately may be grown in a greenhouse temperature, are very handsome, and when there is room some of them must be introduced. Plants with tall stems are rather expensive, but their permanency of character makes them worth the money. Very few would find room for more than half-a-dozen, but even a single pair of Dicksonia antarctica, Cyathes princeps, or Alsophila australis will give character to a large house. Gold and Silver Ferns are very interesting, but they must have warmth, and cannot be wintered in a lower temperature than 60 degs. to 65 degs. Though the early spring is generally looked upon as being the best season for repotting Ferns, there are always young growing plants which require a shift into a larger pot, and this may be done now or any time.

Unheated Greenhouse.

There is a considerable advantage where the house is unheated in having a division wall through the centre of the house, converting it into two instead of one span-rows, one side to face south and the other with a northern aspect. The dividing wall renders the temperature so steady, and at this season and through the summer, when the weather is hot and bright, the flowering plants may be moved to the northern side, and the southern compartments used as the growing houses.

Cold Frames.

Warm coverings will be necessary at night for some time longer yet. All plants that are not too tall will do as well, if not better, in cold frames than in dry, hot

greenhouses; at any rate, the more frames we have now the better. Seedlings of all kinds may be pricked out in beds of soil. There is no better place than a cold frame for Arsen, Statice, and other tender annuals for the next five or six weeks.

Window and Room Gardening.

Some return to now being made for the care bestowed in the winter. Plants which have been preserved in spare rooms are now on the move. Give a thorough dressing with a sharp knife, cutting away all bits of dead wood, with a surfacing of fresh soil pressed well down. Move the plants to the lightest position in the room, and ventilate at the top of the window. Water when necessary, but not too often. Plants in flower will consist of Genistas, Deutzias, Cinerarias, Asaleas, Cyclamens, and hardy Primroses, including Auriculas. The last-named family are easily grown, and are charming things for a shady window in spring. Good pots or musk are popular favourites; these will be making good now. Musk does not want much sunshine. Asaleas, after flowering, are generally a dead loss to most people who have no greenhouse. This need not be if carefully looked after; the seeds and fed blossoms should be removed, and the plant kept in the warm room, the roots kept moist, and the foliage sprinkled occasionally with clean water. In July set the plant outside to ripen the wood, but do not forget it altogether. Neglect in watering will certainly prove fatal.

Outdoor Garden.

Roses must have very close attention now. Insects are making their appearance, and must be promptly dealt with. Tobacco-powder is always handy, and it is worth much to have a remedy at hand that requires no preparation. We are all at times inclined to procrastinate, to put things off till a more convenient season, especially where water has to be boiled to make a mixture. With the Tobacco-powder all we have to do is to take the distributor in hand on our rounds and dust the powder on and among the flies wherever we find them. Suckers must be rooted up. There is more trouble with suckers among worked Roses than there ought to be if the buds had been removed when the stocks were planted. This is another matter in which carelessness leads to endless trouble. How beautiful the Blue Anemone spanziana is now on shady banks where used to a quantity and not disturbed. The Dog's-tooth Violet is another shade-loving plant that is very effective. I do not mean that the Dog's-tooth plant should be placed under trees—the drip and dense shade would be too much for it—but give it a position on the shady side of the rockery; let it have a bed to itself, with the soil specially prepared. It will associate well with the Primulas. Plant Gleditsia which are not yet out; these are always beautiful, but to do them well the soil should be specially prepared. Hardy edging plants of all kinds should be planted now so as to get well-established before the tender plants are set out. I always say use as many hardy plants as possible. Very much more might be done with them, even in the parterre, than is commonly met with. Vicias in sorts may still be planted.

Fruit Garden.

All cracks in the clay of recently grafted trees must be stopped the moment they become visible. This is the best season to plant Fig-trees on walls. In preparing the sites, especially if the soil is of a heavy character, make the border obliquely above the ground level, and work in plenty of old lime rubbish, mixed with broken bricks. The roots like to grow in a mixture of this kind, and the wood will be less gross, and consequently more fruitful. Vines in early and late houses have made wonderfully rapid progress lately. Stopping and tying, and rubbing off lateral buds occupied much time. With the sun shelling all the day long in a clear sky, the work of air-giving has been simplified. What we have to guard against in this bright weather is not to keep the houses closed altogether after the sun strikes the roof. Whenever the temperature begins to rise the atmosphere gets laden with impure air, generated in the closed house at night, and the least bit of air early in the morning will allow the over-heated air to escape. Besides, when the ventilation receives early attention there is never any danger of scorching or scalding, and mildew has a poor field to work upon. Do not leave too many Peaches on the trees a moment longer than is necessary, which means that Peaches should be thinned as soon as the fruit which are taking the lead can be seen. The rule, when the syringe or garden-engine is used freely on fine days, insects do not give much trouble. It is when the trees are neglected, and the borders, perhaps, covered with plants in pots that insects are allowed a free hand. Cherries and Plums under glass must be very carefully managed, just enough fire-heat to keep on covers from being all that is required, and only when frost is expected, or when the weather is damp and cold, when the trees are in blossom that a little fire-heat will be useful. Pines not yet potted should be shifted on as required. There are now three seasons—spring, summer, and autumn—when Pines are overhauled, and reported if necessary, and the beds put in condition. It will be so well to secure some of the plants of the early forced Strawberries to plant out for autumn fruiting. Vicomtesse is a good kind for this.

Vegetable Garden.

French Beans are rather dangerous things now in fruit-houses. If there are any indications of red-spider turn them out at once. If the red-spider get on Vines or Peach-trees they will do much injury. French Beans during early spring should be planted in pots by themselves. Make new plantations of Globe Artichokes in rich, well-cultivated land; they are useless in poor land. Apparagus may be planted now. It is useless to send to a distance for Apparagus roots to make new plantations. If the plants cannot be obtained near seed. The old-fashioned bed system is dying out, I should not advise any having narrow beds to root them up, but I certainly should not add to the number. There is nothing superior to the single-row system at not less than 3 feet apart. Tom-plant must not be crowded. They will be ra' now in a cold pit, if covered with mats at night. It is useless putting out small plants; grow them on teth 5-inch or even 6-inch pots rather than put starved plants with the bottom leaves gone and the trusses of bloom more than a foot from the ground. Early sowing under

glass have had a glorious time for setting their fruit, and the plants are wonderfully dense in consequence of the free ventilation which has been necessary to give to keep down the temperature. It has been necessary to water in Cucumbers even where the means of applying moisture have been practically unlimited. Vegetables on mild hot-beds have been exceptionally good; Potatoes specially so. Horn Carrots have also turored in quietly; but with the bright sunshine more water has been required; but this has one advantage—we have been able to use weak stimulants to advantage. Cut cuttings of Herbe planted, and sow Basil and Marjoram to a warm border.

E. HOODAY.

Work in the Town Garden.

No time must now be lost in planting hardy herbaceous subjects of many kinds. There are many that are most useful of all plants, requiring, when once established, very little care except to be occasionally divided and replanted when the clumps become overgrown and started in the centre, and blooming with great certainty year after year, while very few need now a slight protection to the severest winters. The Irises are some of the very best of hardy plants for town gardens, the German varieties is particular. These have had quite as fine a time of it as London-bridges as ever in this country, and with no special care or treatment. There are a number of different varieties, but beyond the common purple kind, the most valuable of the L. pallida, I. neglecta, I. Squieus, and I. amara groups are all good and very suitable for town gardens. The Saxifrage lately again succeeds remarkably well in town gardens, as a rule, and afford a great variety of both foliage and flower, from the huge leathery leaves and really snowy pink blossoms of S. cordifolia, and S. crassifolia, to the pretty little totts of S. aspera, S. celsa and others. The white flowers of S. longifolia and those of the double-flowering form of S. granulata are very beautiful, and as freely produced in a smoky air in a clear atmosphere, while these are very many other also equally desirable, including the well-known "London Pride" (S. umbrosa). The varieties of Pyrrhodon roosem, both single and double, also make excellent town plants, and the very finely-cut and Fero-like foliage is also very elegant; the double-flowering forms of P. Parthenium are also very useful. Great care is necessary in dividing the old roots of the P. roosem varieties, and, if possible, plants already established to small pots should be obtained. The (Eranthis, or Evening Primroses, again, are good town plants with scarcely an exception, and so are the Veronica, both herbaceous and shrubby, the Dithys of Pink tribe including Geraniums, Finks, swiss Williams, and all the Primulas (excepting only perhaps the double-flowering forms of P. acutilis), though all are not hardy, and several have to be treated as pot-plants. It really seems almost impossible to kill, by its means, the common Auricula (Primula auricula), or to prevent its flowering in any atmosphere, and the new race of hybrid Polyanthus-Primroses are equally vigorous and effective. Do not forget the Japanese Anemones (white and red), Canterbury Bells, perennial Phloxes, Michaelmas Daisies, and the fine autumn-flowering Pyrethrum uliginosum.

B. O. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from April 15th to April 22nd.

Sowed No Plus Ultra Dwarf French Beans on warm border; shall cover on frosty nights if they come up before it is able to leave them exposed. Sowed Winter Greens, such as Broccoli, Curled Kale, Savoys, &c. The seeds were dressed with red lead to keep off birds. I find this answer just as well as covering with netting, and the netting is used for protecting the blossoms of fruit-trees. Looked round recently-grafted fruit-trees to stop insects in the clay. I always use a little short hay, such as is mown from the lawn, with the clay, and this holds it together. Staked, tied, and pinched off side-shoots from Tomatoes under glass. This requires frequent attention now. Pricked off Primula obconica. This plant can be easily increased by division, but seedlings make the best plants; in fact, in the case of every plant which reproduces itself true to type from seeds, or nearly so, seedlings are best. In sowing seeds, select the plant producing the best and finest flowers for the seed parents, and in the course of a few years a better strain may be built up. Last year I had a good deal of trouble with woodlice in my Cucumbers-houses, which arose from using inferior manure; the eggs of the insects, being brought to the house with it, thrived amazingly and gave me a lot of trouble. Up to the present I believe I am quite free. The houses were thoroughly cleaned in winter, and every particle of old stuff swept out, and the walls whitewashed. Greater care has also been exercised in the selection of the manure. Erected up early Primula, heavy loam, with a little better being used. The plants are scarcely by now, and all the Primulas (excepting only perhaps the double-flowering forms of P. acutilis), though all are not hardy, and several have to be treated as pot-plants. It really seems almost impossible to kill, by its means, the common Auricula (Primula auricula), or to prevent its flowering in any atmosphere, and the new race of hybrid Polyanthus-Primroses are equally vigorous and effective. Do not forget the Japanese Anemones (white and red), Canterbury Bells, perennial Phloxes, Michaelmas Daisies, and the fine autumn-flowering Pyrethrum uliginosum.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

Azaleas do. Shifted on Palma. Put in cuttings of Indian rubber (Ficus elastica). I like the Ficus australis even better than F. elastica. It is more refined in its growth, and makes a better pot plant. Sowed seeds of Aralia Sieboldii. I find imported seeds grow the best.

INDOOR PLANTS.

CLEMATIS INDIVISA.

This New Zealand variety of the Virgin's Bower does not appear to be sufficiently known, nor is it cultivated to such an extent as its merits deserve. For a cool-house from which the frost is just excluded it is a most suitable climbing plant, being a fitting companion for such better known subjects as the Lapsagerias. It can be adapted to various purposes to suit each respective case. For instance, if a large break of bare wall in either a greenhouse or conservatory has to be covered, and that as speedily as possible, then this Clematis is well suited as one of the plants for the purpose. It is well adapted also for training over wire arches of an ornamental character, also for

he a thinning process where the shoots are too thick, removing those that are the least likely to produce flowers later on. Insects, on the whole, are not troublesome, green-fly being the most likely to attack the points of the young shoot and thus cripple the tender foliage. The flowering season is from April to May, when a beautiful effect is produced for a long time by reason of the freedom, the succession, and the lasting properties of the blossoms. This Clematis cannot in any sense be considered a difficult plant to cultivate; it is of good constitution, and not very particular as to the soil into which it is planted. I would, however, choose this as good as possible with a view to lasting properties. Fibrous leam with some well-decomposed leaf-soil will suit it well, only using peat when the latter fails to be of good quality. Planting out is preferable to either pots or boxes, for the greater the freedom the roots have the better will be the ultimate results. Whilst in flower and during growth the supply of water should be liberal; but if a late growth in the autumn is apparent, then withdraw the water as a

plant." Not many weeks after it came to me half dead; it was put in a Tomato-house and kept alive, and in consequence of moving, was kept in a room facing east all the winter, with thermometer never above 56 degs. It is now "a thing of beauty," and looks thoroughly healthy, and I shall soon pot it and separate it into three good-sized plants. It is not the Climbing Aspernugus.—SALF.

SEED-SOWING.

Now will be found a very good time for sowing seeds of the approved strains of the Chinese Primula. Where the stock required is but limited, the better way will be to have the mixed packets of seed to save both room and labour. When larger quantities have to be raised, then each colour could advisedly be kept separate. A very good plan for raising the seed is to cover the surface of the soil with Sphagnum Moss in a light manner; should it perchance become dry before the seed germinates the Moss can be easily moistened without in any way washing the soil. Thus covered, a close watch has to be kept, of course, to remove the Moss as germination takes place, so as to prevent the seedlings becoming weakly; it pays well to do this if better results can be ensured. Covering with brown paper and tying it over tightly, as one does in the case of preserved fruits, also answers well, but it must be removed after a few days to watch the progress of growth. Where crickets abound, this latter plan is a safeguard, but in any case to guard against any depredations, it is much the better plan to stand each pan or pot over a receptacle containing water; this will save a lot of annoyance in the loss of young plants. Leaf-mould of good quality, with some light leam and a free use of silver sand, will make a good mixture for raising the seed; peat should be avoided, as there is often a tendency in its use to encourage a green growth that deters the germination of the seed. At this season of the year a moderate heat is advisable, but it should not be at all a dry atmosphere, as, for instance, when standing near hot-water pipes. If the

SEED OF PRIMULA OBCONICA from the first sowing has not provided a sufficient quantity of plants another sowing should be made. There is time enough yet to get good-sized stock. Seed sown last year in the middle of May supplied us with a useful lot of plants that have flowered extremely well. These plants we propose to pot on for another season to see how they will succeed the second year. Unless an early batch of Cinerarias is required, it is not advisable to sow the seed just yet, plants raised very early often run too much to a leafy growth. Celosia pyramidalis sown about now and grown briskly for a time will provide a stock of very serviceable plants for autumn decoration. This will be found better than sowing extra early, the plants probably not having justice done them for want of room when the bedding-out stock has to receive more attention in this respect. Another good old autumn-flowering annual is the Globe Amaranth, which is not grown half enough for August and September use. The purple variety is the best to grow in a general way.

GROWING ON SEEDLING PLANTS.—Those plants raised earlier in the year should all have attention by pricking them off into pans or potting singly into small pots in good time. It is a great mistake to overlook this necessary work; if deferred only a week or two it often results in the seedlings being considerably weakened, a failing that causes delay in the development of a good sturdy growth. Another failing is that of attempting to grow more plants from seed than can be found room for as growth progresses; half the quantity of any kind, when well grown, is far preferable to a larger number of weakly plants. Early-sown Gloxinias should now be fit for small pots after having been pricked off into pens some little time back. These need not be kept in a high temperature,

Flowers of Clematis indivisa.

running up the rafters or columns in large houses. In whatever position it is grown, the young shoots should have a fair amount of freedom. When covering a wall, for instance, as soon as the main-shoots have reached their proper limits, then let the lateral growth hang down as drapery; this will check overvigorous shoots from gaining an ascendency. Upon arches the same plan should most decidedly be carried out, and again when training up rafters. Not only is the growth itself rendered much more ornamental, but the appearance when in flower is greatly enhanced. When trained closely, a large number of the blossoms must be hidden or so crowded together as to spoil the effect as well as the lasting properties of the flowers by the accumulation of moisture. Close training is also a greater encouragement to insect pests, with the greater difficulty of reaching them in the process of extermination. What pruning is necessary should be done immediately the plant is out of bloom, and never during its period of growth; this latter plan means a proportionate decrease in the following crop of flowers. If anything at such times is really found necessary in this way, it should merely

check to the same, such wood not having any chance to become well ripened. Although this Clematis is seen at its best as a climber, it does not follow that it is not adapted to pot culture, for which in reality it is capital. For decorative uses, therefore, in pots it is likewise to be recommended. In the most favoured parts of the country it will, with ordinary precautions, without doubt resist our English winters if upon walls. It must not be confounded with another kind known by the varietal name of *C. indivisa lobata*, which differs slightly in its foliage, but more so in its shyness of flowering, being sometimes disappointing in this respect as compared with the type, of which an excellent illustration is now given, showing one of its many uses. P.

Asparagus plumosus.—Perhaps the experience I have had this last winter with an Asparagus plumosus may tempt others to cultivate this lovely plant. It was given to a friend as an "Asparagus Fern." On seeing it I said: "If you can manage that in your sitting-room window let me know, and I will get one directly, but I have always understood it was a stove-

but they should be as near to the glass as possible, with a light shading during bright sunshine. Later on seedlings should now be fit for pricking off; these will provide a stock of useful plants in the autumn to succeed the foregoing. Cyclamens sown in the past autumn should not have too much heat; neither, on the other hand, should they be trusted yet to a cold frame; this would give them a check. Keep them well attended to for moisture both at the root and atmospherically, and as soon as they need a shift from the small

into 3-inch pots when strong enough. Seedlings make nice, vigorous, and bushy plants, but they do not flower so freely for a few years as those obtained from cuttings.—B. C. R.

PERSIAN CYCLAMENS.

The old plan of cultivating these was to grow on old plants year after year and to dry them off during the summer in the same way as Gloxias, the result being poor examples with very few flowers on them. Contrast this system

Two parts of loam, one of partly decayed leaves, and half a part of peat, adding sand as required to maintain the whole in a porous state. To every bushel of the compost add 2 lb. bone-meal. If the soil is moist, as it should be when used, water will not be required for a day or two; afterwards the roots should not suffer for want of it. Syringe the foliage overhead every day, choosing the evening for the purpose. Toward the end of September the plants should have a position in the greenhouse close to the glass. When the flower-stems appear syringing should cease, or the blooms might damp. The plants will flower principally during November and December, continuing to throw up a few flowers for three months longer.—S. P.

—The plants ought to remain in the greenhouse for another five or six weeks, when they will do better in a cold frame. Keep them moist and lightly shaded, and shift into 5-inch and 6-inch pots by July, and they will all flower well during next December, January, February, and March. Return them to the greenhouse in September.—B. C. R.

A well grown Persian Cyclamen.

pots, do not delay the work of potting into a larger size. A light loam with good leaf-mould and road scrapings will suit them very well. No manure in any form is really needed in the soil; guard, however, against wireworm and the common kind as far as possible. Tuberos-rooted Begonias that are intended for pot culture from seed sown this spring need not be transferred to small pots just yet if accommodation can still be provided by pricking them off a second time into pans or boxes. For my own part, I have always found it best to grow them thus until they are of a fair size, with somewhat more constitution in them. A gentle warmth, with a light shading and plenty of moisture, will encourage a free growth. According to the requirements, the stock of such annuals as Petunias, Mimulus, Stocks, Lobelia gracilis, and other kinds should be looked after for pot culture in good time. Where these are grown for hedging out, it will be a comparatively easy matter to select sufficient of each, and give rather more attention than bedding plants in common usually receive. It pays to grow annuals in considerable quantity if a large show house has to be kept gay during the summer months; it is then an easy matter to throw them away later on to provide room for plants of a more permanent character, thus must in any case be housed as the autumn comes on. H.

3470 — Oytisus racemosus from seeds.—This is a very simple matter. Sow the seeds at once, nearly an inch apart, in well-drained pots or pans in a mixture of light, porous loam, leaf-mould, and sand, with a third or fourth of sandy peat, and if fresh and good almost every one will germinate. They will do nicely in a temperature of 60 degs, but the soil must be kept evenly and moderately moist, and shade from direct sunshine must be given. When 2 inches high transfer the seedlings singly to thumb pots, using similar soil; remove them to a cold frame when established, and afterwards shift

with that now in vogue, which is to sow the seed as soon as ripe, and to grow on the plants in light airy houses or pits in a genial temperature. In this way fresh healthy plants bearing a good head of bloom (as in the illustration) can be had in fifteen months from the time of sowing. The seed, which generally ripens in July and August, should be sown as soon as possible afterwards in a light fibrous soil, with a little leaf-mould and sharp sand. When the seedlings are strong enough, ten or twelve should be pricked off into a 4½-inch pot, and when large enough shifted singly into 3-inch pots, shifting again when these are full of roots. For the last potting stiffer soil is necessary. Attention must be given that the plants when growing are kept quite clean, as if insects are allowed any quarter, the beauty of the plant will be spoiled. Cyclamens, even when not in flower, are ornamental, the markings on the leaves being very beautiful. They are at their best during February and March, as then the flowers have their true colour and the foliage is firm and good. They should have no sticks or ties of any kind. The bulbs should be carefully watered and well ripened after blooming, as the next season's display depends very much on this. The plants should not be repotted until they break into growth, and then they should be put into smaller pots, shifting on as may be necessary. W.

3466. — Seedling Cyclamens.—On a shelf in the greenhouse when they will receive shade during the hottest part of the day is the best place for seedling Cyclamens until the end of May, when a cold frame placed behind a north wall provides suitable quarters; the daily need of shading the frame is thus dispensed with. When the roots reach the sides of the pots, presuming the plants to be now growing in quite small pots, they should be shifted into those 3½ inches in diameter; the strongest of these will go into 5½-inch pots, in which they will flower

3476. — A furnace for a flue.—For a house 14 feet long by 8 feet, or 10 feet in width, a furnace 9 inches square (internally) and about 2 feet in depth from the top or feeding-hole to the fire-bars is large enough. It must be solidly built of good hard bricks and the best mortar, with a very little Portland cement added, and the sides must be 9 inches thick all round. Of course, there is to be an ash-pit (9 inches deep) below the bars, and the exit into flue, which need not be larger than 9 inches by 3 inches, may be placed at the side or back near the top. A damper should never be placed in the chimney where there is a flue, as, of course, when it is pushed in, the fumes from the fire are thrown into the house. I always fix an air-tight door, with regulator to the ash-pit, and check or stop the draught there, for in this case, as long as the chimney draws, there will be no escape into the house whatever. A slate placed against the aperture, with a few ashes thrown up at the bottom to prevent leakage, will answer the purpose nearly as well.—B. C. R.

3464. — Plants for a span-roofed greenhouse.—This is an excellent time of year to start plants of many kinds to flower during both the ensuing summer and winter. For summer flowering you should now procure bulbs of the Tuberos Begonias, single and double, and in great variety of colour, also young plants of Zonal, Ivy-leaved, and large-flowering Pelargoniums, Fuchsias, Heliotropes, Marguerites, double and single Petunias, Marguerites, Abutilons, and anything else you may fancy. Seeds of Chinese Primulas and of Cinerarias also sown now will afford plants to flower during next winter and spring, or you may purchase the seedling plants in June or July, and simply pot them on. The beautiful Scarborough Lily, which flowers in September, should also be potted this month, as well as the Arum Lily, to flower next winter and spring, and there are many other interesting subjects that could not be taken in hand at a better time. Roses already established in pots should now be purchased.—B. C. R.

3472. — Flowers for winter.—There is something wrong in this case. The gardener either does not understand his work or he is not provided with a stock of plants suitable for the purpose. With regard to the kind of flowers available during the winter, you can have plenty of Chrysanthemums up to Christmas, and also Violets grown in frames, and some in pots to place in a greenhouse in bad weather. Then there are the Persian Cyclamens and Double Primulas, both of which furnish flowers that travel well. Freesias may also be had in flower for two months in the dead of winter, and Roman Hyacinths the same. Arum Lilies should also be available. The ordinary Hyacinths and the Double Roman Narcissus can be forced into flower by the end of January; and such Ericas as Wilmoreana and the two forms of humilis flower at that time, and are useful for cutting. At the beginning of March Marsechal Niel and other Roses should be fairly plentiful; but none of these things can be had unless they are managed with a fair amount of skill and in a suitable temperature. Of course a good stock of plants and bulbs must be provided or the gardener will be powerless.—J. C. C.

3465. — Culture of Arum Lily (Calla liliifolia).—The season for the flowering of this

plant extends from Christmas to the end of April, providing a little artificial warmth can be given to it. To have a quantity of bloom from them, though, about Easter-time, no artificial heat whatever is required beyond keeping the frost from the plants. Some persons keep the plants in pots all the year round; but from experience I prefer to plant them out in the open during the summer months. Much labour in watering them is then saved. From now until the middle or end of May, which is the best time for planting them out, the plants should be kept near to the glass in a cool-house, watering them regularly as required. When all fear of frost has passed turo the plants out of the pots; if these were 8-inch ones or more the plants will need dividing; if the plants filled pots smaller than the size named, they will not require dividing, as they will make good specimens the next year. Any open piece of ground will suffice for the summer quarters, digging it deeply, adding a small quantity of manure. A space of 2 feet between the rows, and 18 inches from plant to plant should be allowed. The old leaves will die away, and new ones will form. If the weather be hot and dry, copious supplies of water will be an advantage in assisting growth. Toward the end of September the plants ought to be potted, choosing pots large enough to contain the roots without breaking too many of them. Use a compost of three parts fibry loam to one of partly decayed horse-manure. Allow a space of 2 inches at the top of the pot for water in the case of 10-inch pots, and less for those under that size. If the plants can be stood behind a north wall for ten days after potting should there be no danger of frost, the trouble of shading them will be dispensed with. Sprinkle the foliage over with clear water two or three times each day to encourage a quick root-action. Remove the plants to a light position in the greenhouse, supply them freely with water at the roots when these are active, and when the pots are full of roots liquid-manure given every other time the plants need water will be an advantage. Occasionally wash the leaves with clean water applied with a syringe vigorously. Green-fly is liable to attack the opening flowers; fumigating the house with Tobacco-smoke is the best means of ridding the plants of this insect pest.—S. P.

— If large flowers are wanted, and a succession of them from the same plant, there cannot be a doubt but that planting them out in the ground in the summer is the best plan to adopt. There is, however, a greater certainty in the plants flowering if they are grown altogether in pots—that is, providing they are potted in fresh soil every year in the month of May, and kept well watered all the summer. After the end of May the plants are better in the open air than under glass, and a partially shady place is better than full exposure to the sun. Thoroughly well prepared plants never fail to show plenty of flowers, but even these do not open in mid-winter in a less temperature than 55 degs. to 60 degs., and at the same time they must have plenty of light and air. Strong liquid stimulants must be avoided, or the result will be more leaves than flowers.—J. C. C.

3403.—Treatment of Balsams.—When the first rough leaf is made the plants should be potted singly into 3½-inch pots, burying them up to the seed-levée, but not above. A light yet rich soil will grow Balsams well. For the final potting into 9-inch pots, if large specimens are required, two parts loam and one of freshly-gathered horse-manure provides a favourable rooting medium. At no time should the soil be made very firm. The plants require a lot of water at the roots during the summer; when the soil is made firm it cannot percolate so freely. The hot-bed, with abundance of air admitted to the plants, is the best place for them until they are established in the first-named pots. From there they should be transferred to the greenhouse, keeping them in the warmest end for a few days until they are accustomed to the change. From the small pots the plants should go into those 5½ inches in size, the best of them afterwards being placed in the 9-inch ones; the remainder can flower in those. Copious supplies of liquid-manure should be given to the roots, the foliage regularly syringed, and abundance of air supplied at all times. If available a cold frame after the middle of May provides the best quarters for Balsams. Here

the pots can stand on a cool base of ashes. The foliage can have abundance of light, and be close to the glass, which effectually prevents the growth being drawn up weakly.—S. P.

TREES AND SHRUBS.

LILY OF THE VALLEY TREE (ANDROMEDA FLORIBUNDA).

THIS is one of the best of dwarf shrubs, looking neat and well furnished throughout the year. The flower-buds are formed and considerably developed in the late autumn, so that the little shrub looks throughout the winter as if about to burst into flower; the flowers expand towards the end of March, and remain in beauty throughout April. It is an excellent shrub for a rock garden. The single sprays are valuable for cutting, lasting long in water, and looking well alone, or with almost any flower. J.

TRANSPLANTING EVERGREENS.

MUCH has been said and written respecting the transplanting of Evergreens, some advocating or recommending one time in the year and some another, but after having had much of that work to do or superintend, and therefore some considerable experience of it at different seasons, I am clearly of opinion that April is the best month in which to move large plants, as then the buds are fast swelling and growth just forming, the action of root and top being simultaneous. Evergreens under such favourable conditions quickly become re-established. If transplanted in the autumn, it must be done early, for if they have not taken fresh root before winter sets in, they stand little chance of living, and this anyone may see, for if he only look around now he will find how severely many Evergreens have suffered that have not been disturbed, and what chance than would any have had if they had been moved, as most surely the sap would have been dried out of them and all the leaves have perished? There are some kinds, however, more amenable to transplanting than others, and among these may be mentioned Rhododendrons, Aucubas, Box, and Yew, which generally lift with large balls, as they make plenty of fibre and root near home. Hollies and Barberries are very difficult things to deal with if they are of large size and have not been prepared by previous transplanting. I

dry or suffer more than can be helped. To prevent these things happening, every preparation should be made for getting them into their places or positions as quickly as possible by having holes of sufficient size dug ready to receive them, that the planting may be carried out expeditiously and a thorough watering in quickly follows. For all large plants the watering is a very important matter, as it is impossible to put soil or convey it where water will carry it, and soil should always be washed in that all cavities may be filled, which can easily be done by throwing in the water in quantity with great force, at the same time swaying or moving the head of the plant, which will cause or allow the puddle to draw under and in and around the ball, the subsidence of the whole giving any evergreen shrub a good chance of growth. The final filling in of the soil should be left till the settlement referred to has taken place, and following on immediately after a good mulching be given, which prevents evaporation, and therefore keeps the earth about the roots in a uniformly moist condition, thus greatly favouring the plants. If these are tall, or in exposed positions where they are likely to be affected by the wind, they should be steeled in some way, and one of the best methods is to use three stakes to each plant, and place them tripod fashion with the feet well out, and it matters not then from which quarter the wind may come, one or other of the stakes offers resistance and the plant is kept right. Stout strings applied in a similar manner answer the same purpose, and so does wire, but whatever is used care should be taken to provide against any chafing of the stem where the supports are attached, and the part should be well padded with something soft before the cellophane goes round so as to protect the bark. D.

3485.—*Olematis montana*.—C. Jackman, next to the above, is the hardiest of any in the *Olematis* family, and it certainly is most profuse in the way it gives its blossoms. Another advantage possessed by this variety is that it will grow in any situation; but, of course, succeeds the best where it obtains abundance of sunlight. The first week in February the growth of the previous year should be cut down to within 2 inches of the base. Sir Garrett Wolsley is a purple variety, with a darker bar across each petal, as it flowers from the wood of the previous year's growth but little pruning is

Flowering-branch of Lily of the Valley Tree.

em just now engaged at some, and have a lot to move ranging from 10 feet to 15 feet high. The plants are all got out of hedgerow banks, the best among them being those that have been headed at some distant time, as they have what is here termed a "tod," that is a large bottom, and I always find that such plants feel the lifting less than others, and they generally start off at once. The thing in moving Evergreens, such as

HOLLIES, is to have them as short a time as possible out of the ground, and not to let them

required. Lady Caroline Neville (pale-blue) is free in its flowering propensities and compact in its growth. Flammula has pure white blossoms, small, but emitting a charming perfume, flowering in September.—S. P.

3484.—Pruning of Syringa and Guelder Rose.—Any pruning required should be done during the month of May after the flowers have faded. In trees so young pruning is not necessary. Even if it is it should not be done until the time named, and then only removing a weakly growing branch from the

middle of the bush to give space to those left that the growth will be thoroughly matured, as upon this point depends whether flowers will be produced the next season or not.—S. P.

—No, these shrubs should not be pruned except under exceptional circumstances, such as when they get too large, and then they may be cut back as soon as they go out of flower. Your gardener evidently belongs to the cutting-down race, who prune for pruning's sake regardless of the consequence. One of these men I know has lately sheared off all the beauty from a Ivy-covered gateway by cutting back the Ivy of many years' growth close to the wall, exposing both dead and green branches, which will take years to clothe with growth again in a natural way.—J. C. C.

3482.—**A high hedge.**—As an evergreen screen is preferred, neither Quik nor the Myrobella Cherry will be advisable to plant. The best and quickest growing shrub for such a purpose is Thuja Lobbi; it is far preferable to either of those "O. P. B." names. Plants 4 feet high might be planted without delay, thoroughly preparing the site by deeply trenching the soil and adding manure freely, remembering that the better the preparation given to the soil the greater are the chances of success in obtaining a high hedge quickly. Thuja Lobbi can safely be reckoned to grow 1 foot every year after the first year of planting. It will stand clipping quite as well as Cupressus Lawsoniana, but is not quite so dense in its growth, but will grow twice as fast and will withstand any wind. Holly and Yew make capital hedges, but are rather slow of growth. Laurel makes a capital hedge, but it gets bare at the base in time, necessitating cutting it down to induce it to make fresh growth to furnish the base. Privet grows fast, but does not make so strong a hedge as T. Lobbi, especially if in an exposed site.—S. P.

Honeysuckle and Wistaria in flower.—Allow me to call attention to the fact that here we have the Honeysuckle and Wistaria in flower, and Roses in bud on the house, which strikes me as an unheard-of thing on the 6th of April, in Mid-Devonshire, 500 feet above the sea.—M. C. BURRIDGE HAMBLET.

OUTDOOR PLANTS.

EVENING PRIMROSES (ENOTHERA).

The Evening Primroses are not nearly so much seen in gardens as they should be, their striking appearance and great freedom and long continuance of flowering entitling them to a large share of attention. There are now many fine species and varieties. They should be planted in good deep loamy soil, and in dry weather in summer an abundance of water at the roots is of great advantage, together with mulching. Few plants are better adapted for massing in the flower garden than these Evening Primroses.

HARDY CYCLAMENS.

WHEN the hardy sorts are in the hands of the planter they require perhaps somewhat more care than those are apt to believe who have only seen them growing wild, and more especially in the case with corms that are being planted which have not previously been established in pots. If you are dealing with the naked corms of Cyclamen corm of the age of three or four years, some may be found to have long persistent woody stems, from half an inch to 2 inches or 3 inches long, on top of the corms, which clearly indicate that such roots or corms have been previously grown at some depth from the surface. Other corms, which may be of equal size and age, may not have such long stems, and in the case of these they have assuredly been grown at the ground surface level, and possibly with the corms partly above the surface. Now, as from these long or very short stems (for there are short rudimentary ones, even where they are so short as to be almost invisible) the leaf-stalks spring mainly from the top, but often in the

case of the long ones from the lower parts of the stems, it is quite evident that, whereas those with the very short stems may be planted either near the surface or deeply, you cannot expect success in planting the longer stemmed ones unless they are somewhat deeply buried, to correspond with the conditions under which the stems in their former home came into existence. I hope I have made my meaning clear on this point, because those who have a partiality for the older corms for the purposes they suppose of getting quicker and better effects from size

practically, in nothing but small chips of rock. In all cases the hardy Cyclamen should have well-drained soil, and a good rule to follow would be to set the corms 3 inches deep at least, as then, all other conditions being suitable, they grow more luxuriantly, and last, but not least, afford a better spread of their beautiful foliage, as then, owing to their depth, all the while the underground leaf-stalks are lengthening they would also be spreading, as also the flower-stalks. Fewer corms so planted would cover in a short time a much bigger space than a corresponding number if set nearer the surface. J. W.

An Evening Primrose. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs. Newman, Haslebury, Haslemere.

and strength will simply defeat their own object unless the stemmed corms are planted deeply enough. Some people are all the more likely to err in this matter if they overlook the long-stemmed feature, from having seen many corms, of from 2 inches to 5 inches diameter, cropping out of the surface like black boulders. If these friends will notice such out-cropping corms, they may have an ocular demonstration of the fact that the exposed corms rarely develop stems, and that when they do, it is because they are found in a tilted position with the upper corm centre totally or partially under the surface. By sequence we come now to another feature important to the planter to which the term "tilted," just used, points. The shape of all the species of Cyclamen corms varies, and I believe among all are often to be found those comparatively flat, and often, with so to speak, a depressed ring round the sprouting part of the corm. Now in many parts of land this flat surface or ring tends to hold wet, which during the sunny days and keen frosty nights of our winters affords to frost an abnormal grip, the consequence being that the tissues of the corm often become ruptured, and I believe I shall not be far wrong when I say that such corms newly planted in retentive soil are often killed. A very simple method to prevent this may be adopted in planting. Simply tilt the corms so that the wet cannot lodge. This will not materially interfere with the upward or foliar growths; they will find their way just as well as otherwise, and I believe that it is owing to the accident of wild specimens assuming that position either under or partly above the surface, that the tilted tubers or corms are found to live longest and grow to the biggest sizes. I have watched this habit of the hardy Cyclamen for many years, and there in, I think, something in it. There will doubtless be exceptions, as in the case of those which are found growing in somewhat dry situations, and in very stony soil among the roots of trees or in crevices, and again where they are met with

SPRING FLOWERS.

THOSE who are really fond of gardening do not estimate their flowers merely by their gorgeous hues or the brilliancy of their colouring entirely. Certainly, these things afford a great deal of pleasure, and a bright and pretty garden will always be especially attractive. But the true lover of flowers enjoys the interest which may be attached to a plant which requires to be closely examined before the full beauty of its flowers can be appreciated—a plant which does not challenge attention, but would be passed over unnoticed by the casual visitor, who might thoroughly enjoy the more conspicuous flowers. I do not mean to disparage the beauty of bright and attractive flowers in the open garden, but I think there is a special pleasure in cultivating plants which are distinctly not showy, but are nevertheless most interesting. Such things are especially to be found in our rockeries, but not only there. The herbaceous border is also a place for objects of special interest. At the present time I have in flower on the rockery a plant to which my attention was drawn some time ago by seeing a coloured plate of it.

THE WHITE DOG'S-TOOTH VIOLET (*Erythronium dens-canis*). I had always known the common pink variety. It is to be found in every garden, and it is worthy of a place in every rockery because of the striking character of its foliage. I have found it a shy flowerer. But, to my mind, the white variety is much more beautiful. The extremely delicate texture of its long-pointed petals and the fragile purple anthers, which show themselves when the sunshine induces this little flower to expand itself fully, make the White Dog's-tooth Violet a really beautiful thing. It seems quite hardy, and the spotted leaves at this time of the year are very attractive, but flowers are not generally numerous. Perhaps for that very reason we appreciate them the more when they do come. The plant seems to like a shady nook, and it evidently grows best in a strong peaty soil. It does not like being too dry. The flowers push up from among the tufts of spotted leaves, so that when the former are gone, and they do not last long, the plant is still an ornament to the rockery, as it grows by some old grey stone, which affords it the double benefit of shade and damp. Another flower which comes rather later and would be easily passed over, except by those who like to examine closely the beauty of small flowers, is the tiny little

SOLDANELLA.—This plant seems to like a gritty soil. I remember very many years ago seeing it used as a border to the beds of a so-called "Italian garden." It used to be covered with its pretty little fringed bells in the months of April and May, and the round flat leaves were always green. But this Italian garden was in a very sheltered corner on the south coast of Cornwall. It has flowered with me in this country, but I gradually lost it. It is always difficult to manage small plants which will not take care of themselves to a certain extent. When other plants begin to grow strong and rapidly with warm days, the tiny delicate little things are easily forgotten till it is too late to repair the mischief. I intend to renew my acquaintance with the beautiful little Soldanella alpina. This year I have made a point of comparing the relative advantages of

SCILLA ALPINA AND CHIONODOXA LUCILLÆ.—It seemed to be thought when first this Chionodoxa made its appearance that it was to throw our old friend the beautiful Blue Squill into the shade. We were almost recommended to throw away the old favourite and to adopt the new in its stead. However profitable this might be to

some, it was advice which would have been reins to those who love the frail, but brilliant little plant which, with its sheet of brightest blue, is making our borders and tub gardens lovely in the sunshine of this dry April weather. The *Chionodoxa* has the great merit of throwing up its flowers well, till they look up at you with their sweet little light blue flowers, and seem to ask for admiration as you look at them. But they last a very short time, and ere gone while our old friend the *Scilla* is still in perfect beauty. This is a great advantage in the latter; but again the *Chionodoxa* scores by coming out the first in early spring. I wish I had taken careful note of the time, but I did not do so. I only noticed that in my own garden and very much in the same aspect the *Chionodoxa* was well in flower when *Scilla amona* was only just showing above the ground; but in my opinion nothing can excel the rich blue colouring of the *Squill*—not yet showing the slightest sign of passing away, though it has been in bloom some time. I think perhaps to mix with the bright golden onps of *Crocus* and the pure white of the *Snowdrop Chionodoxa* may be the best, for it can be made to flower at the same time; whereas the *Scilla* does not come till the later *Crocuses* are almost over. Both have the great merit of being exceedingly hardy. *Chionodoxa* especially seems to be one of those things which is not easily nrooted. When you think you have removed all the bulbs, you will find next year straggling bits coming up and flowering with wonderful freedom. I like this early *Chionodoxa*, but it can never take the place of the later *Scilla amona*. Cottage gardens still rejoice in the possession of that pretty little shrub the

MEZERON, which just now is in its full beauty. It may be due to the old days of hedging out, but at all events for some reason this grand old plant is very scarce in large gardens. Its mode of growth is not ornamental, but one can put up with that for the sake of the sweet red and white flowers which are ready to brave frost and snow in the early days of March. In our cemetery there are some fine plants of the white variety, showing how much the cottagers think of it, as they deem it worthy of a place by the grave of some dear one who has been called away. The cylindrical mode of flowering with its red or white blossoms sessile on its rigid stems is almost grotesque in its appearance. It is a pity such an early flowering little shrub is not more abundant in the gardens of the rich, but wa delight to see it and to know how much it is valued in the gardens of the poor. *Tritelia uniflora*, though not actually in bloom yet, will soon be sending up its pretty, stary flowers. They look exceedingly well when planted at the foot of a large stone, where, undisturbed by any interfering tool, they will grow in the Grass and brighten the spring rockery. The ends of the stalks when gathered have an Onion-like smell, but this is too slight to interfere in any way with this little flower either in its usefulness when gathered, or with its general attractiveness. It is an exceedingly showy and free-flowering bulbous plant, and as it has the advantage of being sold at a very low rate, it is just one of those things which might well be used in large quantities to adorn the spring garden.

COLOURED PRIMROSES are just coming into their full beauty. I find the only way to grow these beautiful spring flowers satisfactorily is to sow the seed early, prick the seedlings out when they are nice little plants, and finally put them in autumn where they are to bloom next year. They then make plump heads of strong bloom in the spring. Writers on flowers have repeatedly said that Primroses are at their best the second year. Accordingly this year I made the trial, and I have left some plants in their places for second blooming. The result is a distinct failure. The plants have become tufty with small leaves and a few scattered flowers, quite different from the one-year-old plants which I usually have, and which form one of the chief ornaments of the spring garden. If the plants are to be kept over a second winter, they must, I am convinced, be pulled to pieces and replanted. I should be glad to hear the opinion of other growers of these lovely spring flowers on this point. Those which I hope to be useful next spring are now just getting into their second leaf.

LEOPARD'S BANE (DORONICUM).

ALTHOUGH these are considered by some as coarse, they are free-growing plants, and of much value on account of their earliness and the great show they make on a border, the best among them being *D. plantaginum excelsum*, (figured below), which has big yellow Sunflower-like blooms that are produced at the ends and top joints of each shoot. It is so hardy that cold weather does not appear to retard or injure the blossoms, which last in full beauty a very long time, as they are self-protecting by closing and opening each night and morn. The next in point of merit to the one above named are *D. austriacum* and *D. coccineum*, which are of neat, close habit, and good for cutting from or to grow in semi-wild parts of the garden, for which purpose these *Doronicum* are well adapted, as they not only look natural in such positions, but they can take care of themselves. All the sorts are easily propagated, as they admit of ready increase by division, which may be effected at any time during the winter, or, better still, just as growth commences. D.

3469.—Anemone fulgens.—As you did not plant the Anemones until the time came for them to flower, it is no wonder they failed to please. I advise you to start again with fresh roots, and get them planted out not later than the first week in September. Those you have now growing must be allowed to remain to complete their growth, and afterwards be taken up and kept out of the ground for two months before they are planted again.—J. C. C.

3479.—Lily of the Valley.—Whether the Lilies should be uncovered at all depends on how much the manure has wasted during the winter. Four inches is too much to leave, but if it has wasted down to 2 inches let it remain by all means, as it will nourish the roots, and you will get better spikes of bloom next year if you do not this. In your light sandy soil a soaking of liquid manure will do good once a week during the summer, if you can manage it.—J. C. C.

3481.—Treatment of Crown Imperials.—I do not know to which kind of Crown Imperial this correspondent refers, but I do know that for many years I have been puzzled to understand how it is that the yellow

strongest bulbs is sufficient in one clump, planted about 6 inches apart. The soil should be deeply dug, being stirred quite 2 feet deep to allow of a quick percolation of the moisture from heavy rains. With the natural soil add decayed leaves and old potting-soil freely. Plant the bulbs 6 inches under the surface, covering the ground afterwards with decayed leaves. If the bulbs are strong they ought to flower freely and regularly.—S. P.

3474.—Cutting down Delphiniums.—When I was at the Langport Nurseries two years ago last an nun, where Delphiniums are grown by the acre, Mr. Kelway pointed out to me the difference between those plants from which the flower-stems had been cut down as soon as the bloom was over, and those that had been allowed to ripen a crop of seed. The latter had hardly a leaf left about the old stools, while those that had been cut down early had large tufts of freshly-formed foliage, which quite covered the old stems. From this example I am perfectly satisfied that it is best to cut down the old flower-spikes as soon as the blossoms fade.—J. C. C.

3430.—Annals for show.—Sow the annuals named and others not later than the end of the present month (April), and thin out to 6 inches apart, so as to obtain fine flowers. The ground should be in good heart, and liquid manure will be beneficial as soon as the plants show flower-buds.—E. H.

3477.—Border Carnations.—Do not water the plants unless really necessary, but in a very light and dry soil it may be really required. Water them in the forenoon—about 10 a.m. or 11 a.m.—and then the foliage will be dry before night, and use cold water only.—B. C. R.

3467.—Plants for a shaded plot.—In such a bed as the one described *Calceolarias* would succeed much better than "Geraniums," and *Fuchsias* and *Pansies* better still. If you want shades of scarlet or crimson try some *Begonias* (tuberous).—B. C. R.

ROSES.

SOME EARLY-FLOWERING HYBRID PERPETUAL ROSES.

It is pretty generally admitted that every Rose has its season of flowering, but it is doubtful if this is always sufficiently recognised when making selections for special purposes. I am quite sure there are some cases when it would be decidedly advantageous to know the varieties of Roses that in an average season flower about the same time. Supposing, for instance, one

OUR READERS' ILLUSTRATIONS: *Doronicum plantaginum excelsum*. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs. Brockhills, Clifton Hill, Garstang.

ones thrive amazingly in a cottage garden where they are simply left alone, while I, after giving them every possible care, cannot get them to flower at all. And if I leave them undisturbed the bulbs decrease both in size and number. I hope someone will help this enquirer in a more satisfactory way than I am able to do.—J. C. C.

—Directly the foliage turns yellow and dies down the bulbs should be taken up and replanted into another part of the border, choosing the most sunny spot. Three of the

wanted to exhibit at a flower show held towards the end of June a selection of twelve or twenty varieties and had only room for a limited number of plants, it would be a decided gain to know which varieties might be depended upon to be in flower at that time. Again, it might be that the owner leaves home early in the summer, and would like to see the Roses in bloom before he does so. In either case it would be an advantage to be able to make a suitable selection. With a view to improve my acquaintance with the different characters of the Hybrid Par-

petals, I visited for two years in succession a large grower of these flowers to ascertain what difference there was in their behaviour. Each time I paid my visit towards the end of June. I came away convinced that there is a fairly large number of varieties that can be depended upon to flower in advance of the majority of the same section, and, what is equally important, the quality of the flowers was quite equal, and in some cases far superior to, that of the same varieties later on in the season. Indeed, I am disposed to think that the colour in the dark flowers is more intense than when they are produced under a broiling July sun. I go farther, and say that the

TRUE COLOURING of the darkest Roses can be seen only in the early and late part of the season, unless the flowers are inspected within an hour or two after they expand. Only those who have watched the behaviour of that comparatively new dark Rose, Earl of Dufferin, when it first flowers in the closing days of June can realise its distinct character, as it undoubtedly stands alone as the best of those which bloom early. Of other varieties which I found in bloom at the same time I must mention the following: Victor Hugo was particularly striking. Marie Baumann on out-back plants was also good. In the same line of colour Prince Camille de Rohan is quite reliable. Some good red flowers with different shades of colour will be found in General Jacqueminot, Charles Lefebvre, Alfred Colomb, Charles Felix Britton (intense dark), Mrs. Baker, and J. D. Pawle. The heat amongst the newer varieties having orange or rose-coloured blooms is Mr. James Brownlow, the flowers of which are very sweet and the foliage large and handsome. Lady Arthur Hill is also distinct and beautiful. Caroline d'Arden not only flowers early, but is very fragrant. Alphonse Souperet, Heinrich Schnltheis, Mme. Gabriel Luizet, Mrs. J. Laing, Violette Bouyer, and Mme. de Castellane were in splendid condition on both occasions when I saw them. Bonle de Neige is still the earliest white Rose in this section. Of course there are a good number of varieties that follow those I have named very closely, but I feel sure I have not named any but what may be relied upon to flower early under ordinary conditions of soil and season. While on the subject of securing early Roses, I should like to refer to the remark I have heard from some growers as to the Manetti stock throwing flowers some ten days or a fortnight before the same variety upon any other stock. For some seasons past I have noticed when going through large Rose quarters that there was some difference in the stocks as regards the production of early flowers, but I thought a week was the outside of the difference between the Manetti and the Brier in this respect. I may, however, be wrong in my conclusions. I am, nevertheless, glad that attention is sometimes called to the superiority of the Manetti stock for giving us early flowers. J.

Two good White Roses.—If one were tied to cultivate any one variety of White Rose more especially for forcing, I do not suppose he would choose any other than Niphetos. The two varieties that I propose giving a few remarks upon, however, do not include Niphetos; they are Souvenir de S. A. Prince and The Bride, probably the two finest White Roses sent out since 1844, when Niphetos first made its appearance. Seeing what strides Roses have made during late years, it is saying much for these two varieties when one declares them to be the two best White Tea-scented Roses introduced during the last forty-eight years. The Bride, sent out by an American firm in 1895, is a white sport from Catherine Mermet. For exquisite shape and good size, combined with extra long-lasting powers, I do not think this Rose is surpassed. It is one of the finest Roses grown, an excellent variety for forcing, a good grower, and altogether first-class. Souvenir de S. A. Prince was sent out by Mr. Prince, of Oxford, in 1899, and is, like The Bride, a sport from another grand old Rose only two years younger than Niphetos. Souvenir d'un Ami (1846) is the foster-parent of Souvenir de S. A. Prince. This is one of the very sweetest scented Roses we have, pure white in colour, of grand size and shape, while the plant is of a vigorous constitution. For cultivation out of

doors, I would prefer this even to Niphetos, as it is not quite so delicate and easily affected by the least bad weather, as Niphetos unfortunately is. To all who grow Roses, if only a dozen or so plants, I would strongly recommend this grand white variety, which is equally good in the open air or under glass, for exhibition or for garden decoration.—R.

Propagating Tea Roses.—The present is an excellent time for this operation where plants are forced under glass. Wherever a flower has been cut from a side shoot, the remaining portion of the lateral growth will form a good cutting. Any blind growth will also do for the same purpose, and as soon as they are about three parts ripened is the very best time for the operation. Prepare some pots of sandy soil containing a fair amount of leaf-mould, thoroughly draining these. Remove the cuttings with a small portion of the older wood attached if possible; if not, cut them off clean just under a leaf or joint. Do not remove more than the one bottom leaf. Insert them firmly, give a good sprinkling, and place them in some close propagating-pit or frame. They should be kept perfectly close until rooted; after this has taken place, a little air may be given gradually until they are able to bear the full exposure. Pot on into the same compost, using this a little richer at each successional shift into larger sized pots. It will be well to partially shade the young plants for a short time after the first potting, but after this they may be treated the same as other Roses in pots. Many prefer Roses upon their own roots, and there is no easier plan of working up a stock of this class than by following the simple method here given; and at the present time, and for some two months to come, there will be many opportunities of securing serviceable cuttings. Plants struck now will make neat little bushes for transplanting during the next spring, and will be quite as hardy after a summer's growth as if they had been raised in the open air.—N. S.

ORCHIDS.

THE BEARDED DENDROBE (DENDROBIUM BRYMERIANUM).

Some beautiful flowers of this species come to me from "B. W." He says the plant from which these were gathered is exceedingly gay, having more than forty of such blossoms on it. "B. W." also says that another Dendrobe which he bought at the same time never opens its flowers, but casts them off before expanding. What is the cause of this? The plants are both potted alike, and they both stand side by side. Dendrobium Brymerianum was introduced into England from Burmah by the Messrs. Low, of Clapton, now close upon twenty years ago, and when it flowered it was named in honour of Mr. Brymer; but the plant that drops its flowers was not introduced for some time afterwards. It is known by the name of *histrionicum*, the short-bulbed variety of Brymerianum. Its flowers are smaller than those of the typical plant, and it frequently, as stated, does not open them at all, which is said to be through being self-fertilised; but if that is the case I cannot say, but I do not think it worthy of the pet it occupies, and were I to press a plant as you have done I certainly would consign it to the furnace and cremate it, for it is a very bad variety and not worth growing. However, these short-bulbed plants want to be proved bad before they are cast into the flames, for I have seen some of these produce as good and as fine blooms as those now sent, and until they have been proved they should not be destroyed. And, again, I have seen some of the long-bulbed varieties produce flowers with a much shorter fringe to the lip, and much less bright in colour than those now before me. Dendrobium Brymerianum is a plant which I have found to thrive best in small pots or baskets, which should be well drained. It does not require much soil about its roots, but it likes good exposure to the sun and light, shading only for a little time during the very hottest part of the day. It likes strong heat and a free circulation of air, and to have a liberal quantity of water to its roots, and the atmosphere to be kept moist during its growing season; but when dormant very little water must be given it, and it may be kept much cooler. It flowers at various

times in the autumn and spring; but I think the months of March and April are the true times of its flowering. MATT. BRAMBLE.

DENDROBIUM NOBILE.

I AM asked how to grow this plant by "Gertrude Mansers!" She says that she is so struck with its beauty that she feels that nothing will satisfy her but the possession of a flowering specimen. Well, I am not surprised at this, for it really is an Orchid which excites the admiration of every one, be they professional growers or not. The plant is a very old inhabitant of our gardens, having flowered first in the celebrated collection of the Messrs. Loddiges, of Hackney. It is widely distributed in India, and Mr. Sander has introduced some fine varieties from time to time from different parts of that country. I have before me now, at the time of writing this, flowers of some fourteen or eighteen varieties, all of which are beautiful, and when seen thus together their differences appear more distinctly than when seen singly and at wide intervals. I think the form called *nobiliss* is the king of them all for its size of flowers and depth of colour. *Sanderianum* is another good coloured form which comes close to the noble majesty of my early days. *Cooksonianum* is a wonderful form, having its two petals coloured at the base the same as the lip, and when spread out flat it really presents the appearance of a flower with three lips. Another good form is *Schroederianum*, which is a heavily marked light variety. *Mogans* is a good and pretty flower, *Cypheri* appears to be a large light flower, and *albosans* and *album* I too have before me. The first is a very pretty and distinct flower, whilst the last carries with it quite the mark of the old species in the lip, being pure white in its outer segments. These and many others are all worthy of a place in any and every stove or Orchid-house in the country, and they may be grown in small pots, with one or two flowering stems, or in large pots or baskets, with many stems, bearing hundreds of flowers, and by a little management they may be had in bloom during all the first five months of the year. Now, this Orchid requires its roots to be well-drained whether grown in pot or basket, and it should be potted in a mixture of peat fibre and Sphagnum Moss. I formerly used more peat than Sphagnum, but from recent experience I think this was a mistake. Press it down firmly, leaving the plant sitting upon a little mound, slightly elevated above the pot's rim. When growing the plants should have good heat and be liberally watered, and they should also be syringed overhead daily; but when the growths are made up water should be withheld entirely and the plants removed to a cool but airy house, where the growths may ripen. They should be kept in a dry condition and in the greenhouse during the autumn months and the beginning of winter, when the flower-buds will begin to appear on the two-year-old growths, when they may be taken into a warmer position and a little water given at first; but as the flowers increase in size this element may be more freely administered, and these blooms will in due time unfold in all their beauty. I would advise "G. M." to choose the earliest and most forward plants for the first removal to heat, leaving the other plants in the greenhouse, as by this means she will provide a succession of flowers; but if a big display is wanted of this one plant all at once, why, they must all be started about the same time, and immediately after flowering the plants should be taken in hand and repotted or resurfaced, as they may require it, and be placed in their growing quarters and treated accordingly. I have seen this Dendrobe flower upon its last-made growths with their leaves still upon them; but such plants I have found do not continue to do this, but, as a rule, they pass over a season and then again flower upon the old or second year's wood. A remarkable evidence of this was shown in the pruned plants of this species that were exhibited at the Temple Show of the Royal Horticultural Society last season. These plants were flowering upon the growths last made, which was not natural to them; but I do not know how the same plants stand affected this season. MATT. BRAMBLE.

3394.—Tarring wood.—If ens plant of paraffin be added to a gallon of tar it will dry much quicker, and set much harder and be more durable.—I. GIBBER.

FRUIT.

PEAR "BEURRE DIEL."

THIS Pear is said to have been discovered at the end of the last century at the Castle of Perce, near Vilvorde, now known as the Maoor of Trois Jours, and that until 1819 it was known as Beurre des Trois Jours when Van Mone obtained grafts, and, believing the variety to be unnamed, dedicated it to his friend, Dr. Adrien Diel, of Dretz, in the Duchy of Nassau. There it retains its original name. Here it is well known as Beurre Diel, whilst the magnificent fruit sent from the Continent and Jersey reaches the English market under the name of Beurre Magnifique. The fruit (see illustration) is obovate, of the largest size when grown against a wall, and of medium size from bush or standard tree; is pale green at first, changing to yellow, and is covered with large russet dots and blotches of brown russet; eye with short segments set in an uneven basin; stalk an inch long, short and curved, inserted in an open, uneven cavity; flesh yellowish-white, tender, buttery, and melting; in season from the end of October to the beginning of December, a period now replete with very choice sorts. The

soil, and one of the reasons generally advanced for tree lifting is that the roots have got too deep, a pretty certain thing to happen if trees are neglected, but not if they are looked after at all times of the year. I grow a good many fruit-trees and bushes of all the leading kinds, but the time spent on root-pruning is nil. If a tree gets into an unfruitful state I root-prune with a spade and mattock, taking the tree right out, root and branch, and putting it on the fire, as remedial measures cost more than a new tree, and then the site, after being well prepared, is at liberty for a new tree, and as I always keep a good stock of young trees coming on, no time is lost, for a tree that will bear some fruit the following year can be used, and herein lies the reason why I do not require to root-prune. Supposing that the trees are brought in as maidens, or one or two years old, from bud or graft, or even on their own roots, they are planted out for the purpose of developing into trees fit to transplant into permanent quarters during the next planting season. The roots are carefully spread out near the surface, covered lightly with soil, trod in firm, and then mulched to prevent injury from frost or drought, and when required for permanent planting they will be found to have a

THE KITCHEN GARDEN.

COLLECTIONS OR SELECTION OF SEEDS.

THE rage for collections seems passing away, and the more useful and practical plan of making selections seems gaining ground. This is not to be wondered at, for if the owner or cultivator of a garden does not know what he requires for the season, it is certainly not to be expected that a stranger can make out a better list, and the unanimous verdict of those of my friends who have gone in for collections is that they get a good many seeds that they did want and found useful, but that they had so many that they did not require at all, that it caused the sorts they did utilize to cost them more than if they had selected the kinds they had space and use for, and paid, perhaps, a little higher figure for them. If we take the most important classes of vegetables, such as Peas, that are in most gardens in request for as many weeks in the year as they can be had, we find in practice that it is very difficult to allot the precise quantity that a moderate-sized garden would require, and if that were the only difficulty, it might be got over by having collections rather under the quantity one expected to use, and making up the deficiency from the neighbouring seed store. The question of suitable varieties is even more important than quantity, for in the outskirts of populous towns, where the majority of villa residences are located, Pea-sticks are such an expensive item, that they cost nearly as much as the Peas could be bought outright for, and for this reason all sorts of contrivances in the shape of wire supports are used, or, as is more generally the case, all the tall-growing varieties are discarded, and only the dwarfs, such as American Wonder, English Wonder, William Hurst, and Little Gem, are used. But if there is any difficulty in making up a collection to suit any two gardens without first consulting the wishes of the owner in the matter of such a universally-cared vegetable as Peas, how can you expect to be more successful with such vegetables as are held in the highest estimation in one garden, but never used if grown in the next?—I allude more especially to Parsnips, Broad Beans, Salsify, Scorzoneria, Chicory, and Artichokes—that one finds the packet left unopened at the end of the season, and eventually cast into the furnace. Gardens as a rule are not any too large to supply the household they are attached to, and one of the most important things in the management of a garden is not so much the mere planting of certain crops, although a good deal depends on that, but in making an estimate at the earliest date of what space can be allotted to each vegetable, and what quantity of seed will be required, allowing for casualties incidental to our variable climate. H.

Pear "Beurre Diel."

tree is a vigorous grower, attaining a large size, hardy, a most abundant bearer either as a standard or upon a wall. Fruit grown in the latter mode is often inferior in flavour to that produced by standards, dwarfs, and espaliers, though brighter and of larger size. Being so reliable as a cropper, surplus fruits of Beurre Diel are invaluable for cooking, a way in which many dessert Pears are extensively used. C.

ROOT-PRUNING VERSUS ROOT-LIFTING.

If we may judge of the amount of root-pruning done by the number of articles written on it one need go no further to seek for the cause why fruit crops are so frequently below the average, for the youngest novice in the art can tell you that only trees that are well established at the root can bring crops to perfection, and certainly no surer plan of defeating the very object for which fruit-trees are planted can be invented than that of perpetually disturbing the roots. It is like children's gardening when the plants are lifted and replanted nearly every day to see how they are getting on below the surface. Yet one need not dig up a tree for this purpose, as the growth it makes, or the character of the fruit it produces, will tell as surely what kind and quantity of roots are below the surface as any practical fruit-grower as if the tree were lifted bodily out of the

mass of fibrous roots, and the wood will be of that medium strength that can hardly fail to be fruitful. But this could not be done so well if the trees had to travel long journeys by rail. Careful planting is a great safeguard against deep rooting. Whatever direction is given to the roots they will continue to follow it for years, and large, but not deep, holes to receive the roots should be prepared before the tree is lifted. Put rough turf or loam under the tree, and spread the roots out in all directions, but do not bury any of them more than 6 inches deep, and keep a good mulching over them, and see that they never get dry. If any tree grows too strongly lift it and replant it again, which will usually be all that is necessary to insure good fruitful trees, but if any after that do not repay the care given them with good fruit, grub them out and start afresh, for it is only wasting valuable time to try to coax some trees into fruitfulness. If the stock is healthy, however, it may be headed down and grafted; but if any signs of canker are visible, or the young wood dies back, grub the tree up and start afresh. J. G., *Hants.*

Caterpillars on Gooseberry trees.—In answer to enquiries in GARDENING, I have never had these pests since I planted Broad Beans in rows between the trees. Before then the trees were sown up with them; but this remedy was suggested by a friend, and at once acted upon with the greatest success.—M. L.

Neglected vegetables.—Dining lately

in Shropshire with the vicar of a country parish, I was delighted to see the Common Dandelion (*Taraxacum officinale*) served as a vegetable. The first leaves had been pulled before the flower-buds had begun to appear, and were then plainly boiled and served on a set like Spinach. The result was a very delicate vegetable, with a distinct trace of bitterness, but one not so pronounced as to be at all unpleasant. Just at this moment, too, the tops of the Common Stinging Nettle (*Urtica dioica*) are coming to their best. At the close of winter, in the first weeks of spring, is the period when fresh green vegetables are most scarce, and it is at this period that the claims of the Nettle and the Dandelion deserve special notice. Growing by the wayside and on waste plots, they cost nothing to produce, and, so far, free from the pampering of a plethora of manure, which market vegetables too often get, they are of a healthier texture. Peaching up in hedgerows and sheltered corners before any other vegetable, they come, not only as a food, but as a better substitute for "spring physic." If all our country clergy would follow the example of the one I have mentioned, and not only preach domestic economy, but put it into practice in those little things wherein it is of most value to their poor parishioners, we should have less occasion, in praising our thrifty Continental neighbours for making a good dinner out of a basket of wayside herbs, to condemn our own

peasantry, who too often live in the frying-pan. Some of the water in which the Dandelions or Nettles have been boiled may be poured on to Oatmeal and eaten as "brose," and thus those properties which are of special value for purifying the blood will not be lost.—M.A., B.C.L.

Leeks.—It has occurred to me that many amateur, and other gardeners, too, may now be throwing away surplus Leeks. Few seem to know what an excellent dish Leek bulbe make. A hint to them might be timely.—JOSKIN DICKINSON.

HOUSE & WINDOW GARDENING.

SIMPLE HOUSE DECORATIONS.

We can never be too simple in our use of plants and flowers, especially when we essay to ornament or decorate our homes with them. The finest of plant growth is too sacred, the loveliest of our flowers too precious to be wantonly and wastefully employed, no matter how great our joy or how deep and desolate our sorrow. Of late years there has been an unwholesome rivalry in the reckless use and inordinate profusion of flowers as used for functions and festivities of all kinds. It is to be hoped that the extravagant Second Empire sort of profusion and wastefulness of flowers has been ended, and there are already signs of this being done, and with the best results, for the true and most satisfying use of flowers, dainty or simple, can never be measured by their cost in the market, by their rarity, or by the difficulty or expense of growing them. Flowers in variety and in plenty let us have by all means, but it surely is not at all necessary that choice Orchids and rare Pithier-plants should be frozen to death on icy rockeries or frizzled up by the heat of gas-light in order that we can enjoy their exquisite beauty. Only a few years ago and the pendulum swung in the other direction, and it was hereby in many gardens to cut a flower. As an illustration, we have only to go back to the days of show plants, when in many gardens plants were mainly grown for prize at the horticultural shows, and the actual owner dare not cut a flower from them. There is a story told of a well-known lady who, half a century or so ago, was the acknowledged queen of horticulture in London, and her splendid collections of choice plants were rarely to be surpassed as exhibited at the metropolitan floral exhibitions. The *Amhectia nobilis* first flowered in her hot-house, and her triumphs were many, but she could not be induced to cut her commonest flowers, and when importuned by friends whom she did not like to refuse, she generously sent them lovely bouquets, &c., which she had purchased in Covent-garden-market. The real delight given to us by flowers bears but a small proportion to their rarity or profusion. The commonest of flowers after all possess the greatest charm, and a duchess or a princess even who would scorn a bouquet of Orchids may be moved to tears by a handful of Violets or Primroses artlessly offered to her by a cottager's child. In the old show plant and bedding-out days, indeed, there were very few flowers to cut or use in any homely and simple way. Now, however, we have plenty, from the Snowdrops and Violets of spring to the Christmas Roses and Chrysanthemums of winter, and even country people having neither hot-houses nor gardens of their own may find an abundant supply of wild flowers, green or bronzed leaves, or hedge fruits many and varied, and need never allow their flower vases or glasses to be empty a single day throughout the year. Here in Europe we scarcely ever think anything pretty except it be something in the way of a flower. In Japan it is different, and leaves and stems set with huds of different kinds are there used with excellent effect. The branches of many trees may be used as room ornaments at this season, and afford a welcome and restful change from eternal floral arrangements, even although they be of various kinds of flowers. Willows, Elms, Maples, Alder, and Sycamore, or branches of Pine, Fir, Laroh, or of Anonba in herry, of Shepherdia, Cornus, or Garrya are each and all distinctly beautiful and effective if artistically placed in fresh water indoors. Branches of Apple and Pear, Cherry and Plum, or dark gnarled spurs and shoots set with rosy almond buds and blossoms are exquisite when simply arranged in the light and warmth of a sunny room. In the exquisite use of such simple and

beautiful things the Japanese have taught us much, and we might well imitate their subtle methods, at least now and then, even if only as a relief and change from our usually flowery bouquets and glasses of hlossoms and Ferns. Now and then try a few bunches of Almond or any fruit-trees in a large vessel of water just as the huds are hursting open, and watch the effect. Last year I decorated a reception room and never need a single flower; all the pots and vases used were filled with branches and leaves only, and the cool and quiet effects were much admired. Again, last winter I decorated a dinner table with nothing but dead leaves, &c., with the brown panicles of *Antilbe rivularis*, and it was much liked by all who saw it done. The brown winter leafage of Ivy, Tellima, Bracken, and Royal Ferns is admirably adapted for such use, and looks well under artificial light. What we especially require in our home decorations is variety—some constant changes of an agreeable kind—and it is here that the floral artists of Japan are superior to our own. There is no forcing nor retarding of flowers in Japan as with us, and so it follows that all their productions are at least seasonable, and one is not wearied by too long a continuance or the repetition of the same things. I have seen a room most tastefully decorated by the hostess herself in less than an hour, the only materials used being fresh green Pine branches and their brown cones, relieved here and there with dead Fern fronds, chiefly those of *Osmunda regalis*, 8 feet long, and of the most beautiful fox-brown tint imaginable. In early winter I have seen branches thickly set with crimson haws and wild Rose and Sweet Briar stems with scarlet hips need with exquisite taste as relieved with the bronzy follage of *Mahonia aquifolia*. Indeed, I sometimes thought that we have, or use, too many flowers in proportion to the use of stems and leafage, but, at any rate, it is quite possible to artistically decorate a dinner-table or a suite of apartments without a single flower being used. This is a fact not often grasped by those on whom the execution of room decoration usually falls, and the constant and but little varying use of flowers and hot-house Ferns, often the same in kind, leads to a sameness not a little depressing to those familiar with the variety of material and the range of variation possible in its tasteful and proper employment. It is the same with plants. A healthy Palm is always a lovely and graceful thing, but it is the constant repetition—the eternal sameness—that irritates and annoys one, for that variety is life some of me at least believe. Let us have variety in our room plants, as also in our flowers, and the result will be a gain. A fresh, glossy-leaved *Aralis*, an *Aspidistra*, a group of green-leaved Dragon-trees (*Draecena*), a hanging-basket or two of fresh green Ivy, or of the creeping Fig, all or any of these would give us a much-needed change. By all means let us have Palms in plenty, Phoenix, *Latania*, *Corypha*, and *Cocos*; but Palms alone in time become tiring, and it is then that the wearied mind calls out for variety. This relief the Japanese obtain by using things only in season. Natural things as thus used can never weary, and our own plan should be to go more direct to garden, field, and wood for our floral and leafy decorations, and to use them holdly and simply.

3473.—Artificial manures.—Guano may be used to a moderate extent, but as an all-round fertilizer for purposes of this kind I know of nothing to equal Thomson's Vine and plant manure.—B. C. R.

2438.—Nerine sarracensis.—When the growth is completed the soil should be gradually kept drier than when in full growth to induce the bulbs to ripen thoroughly, and thus produce flowers the next year. If the roots are in a satisfactory state, and the pots of fair size, say, 4 inches in diameter for one good bulb, repotting will only be required every other year.—S. P.

3330.—Anemones from seed.—I received the following directions for sowing "St. Bridgid Anemones," and succeeded very well. My bed was a mass of lovely blooms for months, last spring and summer, and they are just beginning to bloom freely again now. Clear away 15 inches of the old soil from a bed, fill in with cow manure, add 4 inches fresh mould from a field, sow thinly, cover lightly, water when dry. This out as soon as plants can be handled; the thinnings may be planted again in another bed. I found they moved very well. I thought them well worth the trouble of preparing the bed, and I had no fresh field soil.—BULL.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *Gardening* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37, Southwark-street, Covent-garden, London. Letters on business should be sent to the Postmaster. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to queries inserted in *GARDENING* should mention the number in which they appeared.

3404.—Water Lily seed.—Would "A. H." kindly say where Water Lily seeds can be got?—I. L.

3405.—Culturs of Justicia and Eupatorium.—A few hints on the culture of *Justicia carnea* and *Eupatorium aceroides* will oblige.—D.

3406.—Planting Asparagus.—Is it too late to plant two-year-old plants from 1st to 20th of April? What is the best time for planting?—W. H. D.

3407.—Peas for show in July.—At about what date should Californian Wonder Peas be sown to be ready for exhibition the third week in July.—HON. SEC.

3408.—Planting Freesia-bulbs.—Which is the best time for planting Freesia-bulbs in Norway? May the soil and treatment be the same as for *Hyacinth*?—NORWAY.

3409.—Eucharis bulbs.—One out of some two dozen *Eucharis Lily* bulbs recently potted has sent up a flower-spoke, with two rather small flowers on it, and no leaves. Is not this very unusual?—ACTON-TOWN.

3500.—Hardy Water Lilies.—Will "A. H." be good enough to say where Hardy Water Lilies of the *Millicca* kinds can be purchased, and if they are to be obtained at moderate prices?—H. G. WHITE.

3501.—Rooting cuttings.—I have a large *Heliotropis* over the back of a vinery. I want to take many cuttings for bedding out this summer. Will someone kindly say the surest way to propagate these?—F. H.

3502.—Bulbs after flowering.—I have a quantity of bulbs now in flower in the garden. What shall I do with them when over? They are *Crocuses*, *Tulips*, *Hyacinths*, *Double Daffodils*, *Snowdrops*, *Winter Aconite* and *Sollas*.—LAUREL.

3503.—Jerusalem Artichokes.—What treatment is necessary for growing Jerusalem Artichokes in Norway? Are they propagated from roots, cuttings, or seed? Will a northern aspect, with rather heavy soil, agree with their cultivation?—NORWAY.

3504.—New Zealand Flax.—When is the best time to plant New Zealand Flax, best soil to grow it in, and how should it be treated? Will it grow from suckers (pulled off from the old stools) without any roots? Locality, Ireland.—EROLAND.

3505.—Improving a lawn.—Will someone advise what to do to improve a lawn? It is taken in from a field. At present it is a collection of weeds. I am using lawn sand to kill them. Would it be a good plan to water now with guano-water, diluted?—W. W.

3506.—Liquid-manure.—Will anyone kindly tell me at what rate I may safely use a mixture of pigeon-manure and soot as liquid-manure for such things as *Begonias*, *Narcissus*, *Lilies*, &c., in pots? Could I use it safely for *Maiden-hair Ferns*?—A. YORNBURGH.

3507.—White Lilies for market.—Would anyone kindly inform me how to grow for market White Lilies to have them in flower from the month of December to March? Full directions where to procure the cheapest bulbs, and how to proceed in growing will much oblige.—J. A.

3508.—Seedling Panicle.—I am growing some seedling Panicles, and I want to pick out the best and give names. What are the chief qualities to look out for? Could I expect exhibition blooms from this year's seedlings? What treatment do they require?—ALBERT STR.

3509.—A lean-to greenhouse.—I have a lean-to greenhouse against a south wall, with no heat. Can I grow *Chrysanthemums* in it so as to have a good show? Is it too late to start? If not, I shall be so glad of hints as to best kinds, where to procure, and how to treat?—LAUREL.

3510.—Apricot trees against a south wall.—I have two Apricot-trees against a south wall. As yet they have never borne more than four fruit. The trees are large and healthy. They are now setting a quantity of fruit. Would it be wise to syringe with clean water?—G. C.

3511.—Plants for a trellis-work.—I am erecting a trellis-work across a border from north to south, to break the force of the east wind. Will anyone kindly tell me the names of a few suitable climbing plants (flowering) which would stand out permanently, and when to plant same?—HON. SEC.

3512.—Plants for market.—Would anyone kindly tell me the best way to propagate and grow for market these plants: the India-rubber-plant (*Ficus elastica*), and *Aspidistra lurida*, and *Acacia Iopanthus*? Full directions will much oblige. Also, what is the best Maiden-hair Fern to grow for market, the best way to grow it, and how propagated, whether by seed or splitting up? Also, what are the best *Palmariums* (*Begonia*) for force for market, and what are the earliest flowering single *Zonitis* to flower?—J. S.

3513.—Treatment of Tomatoes.—Would someone kindly tell me if it would be any benefit to my Tomatoes to cut off the bottom leaves to about the second joint, and would it strengthen them to do this, or would it be best to leave them on?—A. CONSTANT READER OF GARDENING.

3514.—Nasturtium and annual Sweet Peas.—Will anyone kindly inform me what best should be used in a greenhouse for raising these, and at what height, and when should they be planted in the open ground, and the best way to harden them off?—W. M. LUFFS, Birmingham.

3515.—Chrysanthemums against a south wall.—I should be glad to know what Chrysanthemums would do best against a south house wall, sheltered from north and east in Rutland, when they should be planted, and if they will flower in winter by being sheltered at night without heat?—H. M.

3516.—Plant for a centre of a bed.—I wish to have a centre to a bed in a formal garden in the shape of a handsome neat plant. I thought of getting a Cactus, but perhaps someone might suggest something harder and as effective? I wish to put it in position about middle of May.—C. B. J., Aldershot.

3517.—"Spot" on Gooseberry-trees.—What can I do for my Gooseberry-trees, which every year become covered with a red spot on the leaves but on the fruit? It is the first year of old bushes, but has now come on. The young ones as well. Is there a cure for it, or is it something in the soil?—Mrs. PULLOCH.

3518.—Treatment of Seakale.—I have a few lots of old Seakale in my garden, and it is growing too high for covering up to winter. Can I cut the old stumps down in a level with the ground, if so, will the roots grow again for cutting next spring for the table? Also, can I plant the cut-off stumps, which will be each about one and a half feet in length?—ENGLAND.

3519.—Treatment of various plants.—I should be greatly obliged to any of your readers to give me some information of the treatment of the following, also the time of flowering, colour, and if any scent of the flowers. They have been sent me as a present. Rhododendron Falconeri, Leptospermum Lunigerum, Callistemon rigidum, and a plant which looks like "Southern wood."—S. L.

3520.—Small greenhouses.—I have a few small greenhouses all well heated with 4-inch pipes from one boiler. I propose to grow Cucumbers for market all the year round. Do they fruit well enough in winter to pay the cost of fuel and labour? Also what other salable vegetables or flowers could I grow in the same houses with them during the year requiring the same heat and moisture?—J. D.

3521.—An old Asparagus-bed.—I shall be very glad of advice as to the treatment of the above? It has been much neglected, having a good deal of Couch Grass and other weeds amongst the roots. Would dressing of salt remedy the evils mentioned, and if so, what quantity per yard? Or would it be better to make a new bed? When should be sown, and ought it to be sown where the bed is to be made?—ANAKOUSA, S. Yorks.

3522.—A lean-to greenhouse.—I have a lean-to greenhouse 10 yards long by 4 yards wide, bright at top of roof 11 feet, the fall being 8 feet at the side of my house facing due east with one end facing south, which gets all the sun up to 1 o'clock in the day. The house is unheated, but with windows leading out of a warm kitchen. Can I grow Tomatoes in this? And if so, what sort would do, and when should I start?—W. B.

3523.—Layering Rhododendrons.—When is the best time to layer Rhododendrons, and how should it be done? When is the best time to plant the rooted layers, and also young trees I intend to purchase from a nurseryman? Will they grow in a good maiden loam as well as peat, and under Beech-trees? I have been told that nothing will grow under Beech-trees—that the leaves are poisonous to plant life. Is this so?—ENGLAND.

3524.—Roses from cuttings.—I am wanted to grow some Roses of all kinds from cuttings. Will "J. C. C." or anyone else kindly let me the right time to put in the Rose-cuttings, and how they are put out—whether in trenches with a little sand or in cold frames—and how many eyes should be left out, and how many batches I can put in this year, and what is the best situated spot for them in the garden, &c.?—CONSTANT READER.

3525.—Planting Raspberries.—In planting a fresh lot of these last autumn I followed the advice of "M. J. Wright," given in his work entitled "Profitable Fruit-growing for Outdoors, &c.," and put the canes in about 12 inches apart in rows—they appear to be very close. Will any grower tell me if they have tried this way of growing Raspberries, and with what result? Also their treatment of the canes after the first or second season?—E. YOUNG.

3526.—Laying out a flower-bed.—What would be a pretty and gay arrangement for a long flower-bed against the house, broad in the centre and narrowing off at each end; aspect, south-east; locality, Norway? Last year I had Giant Sunflowers and Dahlias at the back, then Scarlet Lobelias, then Pelargoniums of every kind and colour (single), then Yellow Eschscholias, then Blue Lobelia. This year I should be glad to have a thorough change, but an equally gay one.—NORWICH.

3527.—Vines dressed with paraffin.—I have several old established Vines in my viney (about thirty years old); they suffered from mealy-bugs a few years ago, which, although mostly destroyed, still showed signs from year to year. When pruning them the seed of last November my gardener dressed them with paraffin; the Vines commenced breaking out apparently all right in March, but after striking the young buds seem to wither off, and little life seems to be left in the canes, though the buds and the little leaves which have appeared look green, so that the canes themselves seem not to be dead. Would someone be so kind as to give me some advice whether Vines which have thus suffered by paraffin poisoning can be treated by any antidote to counteract the evil, or whether the Vines are past hope and only to be destroyed? I may add that the roots are partly in and partly outside the house.—B. BRICK.

3528.—Treatment of Palms, &c.—I should feel much obliged if someone would kindly tell me if there is any particular manure I could give Palms, Pteris Fern, and Aspidistras planted in Jardinère, kept indoors, but are frequently moved to a warmed conservatory for a change. They are well cared for, spanged, watered, and free from draught. As they are not thriving I would much like to know what treatment may be beneficial to them? Do they require repotting?—M. A. C.

3529.—Black Hamburgh Vine.—I purchased a Black Hamburgh Vine in March 1891 as a fruiting-one, and planted it, spreading out the roots and cutting it down to within 12 inches or 14 inches of the ground. The house is a cold or rather unheated greenhouse, well sheltered, facing south-west. The roots are all outside, the cane being in the house. The Vine grew fairly well, and I cut it back to the level of the glass. Last year I let it grow two branches, which I pruned back, leaving one 3 feet, the other 4 feet or 5 feet long. This year every eye has broken, but no sign of fruit. What ought I do? Should I let it grow as it likes, or confine the growth to one or two branches? I sowed a few barrows of stable-manure over the roots but did not water it much.—H.

3530.—Garden frames.—I am about building a permanent pit for growing Melons and Cucumbers, and keeping plants over winter, such as Cinerarias, Primulas, "Gevanium," and Calceolarias cuttings, and for raising half-hardy stuff in spring. The size of each frame is 4 feet by 6 feet, and I mean to have six of these in one pit. I intend to build with stone, and afterwards cement the walls inside and out. But about the heating is where I am confused, having nothing but stable-manure. How can I keep up a bottom-heat of 70 degs or 80 degs for the Melons, and how can I keep up heat through the winter to rest fruit? Can the pit be built in any way to do this, or can I procure a heating apparatus to do it? If so, how deep must I have the pit? I would like to work the stable-manure, if it would do. I should esteem it as a favour if any practical person gave me some definite advice.—ENGLAND.

3531.—Malmesbury Carnations.—My Malmesbury under glass are usually very successful, but lately a great many of them have been deformed, like those I send with this, by having what appears to be a bud in the centre of the flower. The plants on which this most frequently occurs are young ones sown in July last, and brought on in heat through the winter. I shall be very much obliged if you or any of the readers of GARDENING can tell me the cause of this disease, and the remedy; also how to prevent it in future? I am careful to keep the plants as free from aphid as possible, but have noticed tiny black insects inside the petals occasionally. I am anxious to keep Malmesbury in bloom all the year round; of course, by a succession of plants. Those I have are the original, pale-pink kind, but I wish to know the names of all the different varieties—the deep-ruby pink and crimson—and if there is a real Malmesbury in yellow? I know the Germanas, Tree-Carnations, also whether these varieties are as free-bloomers as the pale-pink? Any information on the subject will be thankfully received.—ORCHARDS.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3532.—Orchid eaten by snail (Charles Stephens).—This is the secret you complain of. One or two specimens of Zonites albaria being concealed in the Sphagnum you employed, it would appear to me that you have introduced them with the green fresh Moss. You must search for them sharply sifter dark, at which time they come out to feed.—J. J.

3533.—Polycaotus bifloris.—A. Morris sends me this plant for a name, which I now give. This is a beautiful species, the flowers being bright-purple and very showy; then its habit of producing them so early in the season makes it doubly useful. I should be glad to see some special growers of the pretty plants again in spring up. This species is a native of Honduras.—J. J.

3534.—Hemantia deformis (H. S. H.).—Your ugly bulb-producing truss of white flowers as entitled in the species named above. It is from the colony of Natal, and it is scarcely worth growing except for its ugliness. There are, however, some beautiful kinds, of which H. Kalmbergii, H. multiflora, H. cinnabarina, H. Manol, and others that are beautiful and showy plants, and to these add such-like plants I would direct my friend's attention.—J. J.

3535.—Mina lobata (J. Dittman).—You should sow the seeds at once in slight warmth, and keep them in pots in the greenhouse until about the middle or end of May. Then plant them out, placing tall stakes to form a pyramid. In this form it will make a very handsome mass some 12 feet or 18 feet high, thickly furnished with its deep-green trilobed leaves, and its sprigs of the reddish-yellow flowers, which, although not useful, are a very agreeable colour. The plant, nevertheless, does belong to the same order. It is like bright sunshine, and it is well suited for covering the side of an arbour. I hope the plant will continue to maintain itself in cultivation. It was growing in our garden in 1842, but it was lost until reintroduced by Meera Haago and Schmidt, of Erfurt, in 1886.—J. J.

3536.—Odontoglossum Alexandrie.—H. B. F. sends some flowers of this species, asking why they are so thin and narrow? I cannot congratulate my friend upon these, for they are really a bad lot; indeed, I may say they are the worst examples I have seen. He has evidently gone in for a cheap lot, and they have turned out a failure. One good flower would put all into the shade completely. If he wants good varieties, take my advice previously given, buy them in flower, and you will have to give more for a single plant than you say you did two years ago for the dozen which you have. I should imagine that the plants that had already flowered when you bought them, and that they were the refuse picked out of a lot. You have no redress. They were sold you for O. Alexandrie, and that is what they are; so you have no way out of it, and, beside, the price should have told you that nothing of any good could or would come out of them.—M. B.

3537.—Canarina campanulata.—T. Bates sends a specimen of this plant, asking its name and culture. The season is rather late for its flowering. I have rarely seen this plant since I was a boy, when it used to flower in the month of February. It was a plant that was a great favourite of my first employer. We used to grow it in a mixture of peat and loam made sandy, and during the winter months it was kept in a warm greenhouse. It is a native of the Canaries.—J. J.

3538.—Broughtonia sanguinea.—J. Edmouison, says he has just received a small box of these plants from Jamaica. They are in capital condition. He asks how shall he treat them? Well, I should advise him to put the plants upon good soil and well-seasoned blocks of wood, almost filling each with plants. Bind on with them a little Sphagnum Moss. It is a plant that likes a great amount of sunshine, and a nice moist atmosphere, and, providing it is last thing is accorded it, it may be exposed to all the sun that shines, saving just in the hottest part of the day.—M. B.

3539.—Rudgea macrophylla (G. Hornaby).—This is the name given by Benthams to the specimen sent, and its native place is said to be Rio do Janeiro, though most of the kinders are said to be native of Guiana, and this plant enjoys a strong heat. These plants are all shrubs or trees, this species being exceedingly ornamental, producing large heads of pure white flowers from the points of its shoots, which are finely set off by its large deep-green leaves. It is a plant that soon rises upon a stem, but it will break cutting down, and it will break out and make a bushy head. It thrives in a mixture of loam and peat made sandy, and when growing it likes an abundance of water. I am not surprised that you think it is a grand plant.—J. J.

3540.—Maadewallias (W. F.).—Yes; these are very beautiful flowers, producing such vivid colours, and the majority of the kinds are very easily grown, too. First of all they require to be placed in a house with a northern aspect, where they can get an abundance of air and shade, and they also enjoy an ample supply of moisture to their roots and in the atmosphere. Treated in this manner and kept in a temperature which does not fall lower than about 48 degs, they will do well, and in the summer time keep the isopetrous down as much as possible by damping down and shading. The following half dozen I recommend you to get: M. amabilis, David, Harry, and in varied colours, to a variety of roses, and Vichy. You will find these all gay-coloured kinds, and worthy the attention of every grower of Orchids.—M. B.

NAMES OF PLANTS AND FRUITS.

Names of plants.—T. G. Tansley.—Magesea cordifolia.—Dergha.—1, Davallia canariensis; 2, Adiantum gradifolium; 3, Adiantum concinnum istum, apparently rather dried up; 4, Send fertile frond.—White Lily, 1, Phaiodolium aureum; 3, Anemone bulbiferum; 3 and 4, Send fraser and fertile fronds.—J. W.—1, A Zygopetalum apparently, but specimen crushed up to packing; 2, Cryptomeria japonica; 3, Thuja; 4, Cupressus Lawsoniana viridis; 6, Santalium Indicum.—D.—Allium.—Miss Wilson.—Miss Wren.—Bird Cherry (Prunus Padua).—A. A. Ananar.—Aspidistra, Aspidistra Drummondii; 2, 3, and 4, Send in flower. Impossible to name from such tiny scraps without flowers.—Erin.—Send better specimens.—T. P.H.—Impossible to name from such a little shrivelled-up piece of Orchid-bulb. Send when in flower.—Drake.—Looks like Asclepias Ortoides, but flowers were much crushed.—An Old Reader.—Forsythia suspensa.—Mrs. Byndman.—Narcissus cyclamineus.—A. Robertson.—Ferns quite unrecognizable, though being packed in damp grass.—W. M.—Both are specimens of Teucrium (Bignonia) redicans apparently.—S. G. Smithey.—1 and 2, Polyalolum angulare; 3 and 4, Butea Oryzalis speciosa.—H. D. B.—Ascia verticillata.—Cymbidium Lowianum.—Sandiford.—Bird Cherry (Prunus Padua).—A. J. Hardcastle.—Rose sent had all fallen to pieces.—Tola.—Magesea cordifolia.—W. Wren.—1, Grape Hyacinth (Muscaria botryoides); 2, Glory of the Snow (Chionodoxa Lueddigi); 3, Specimen too much crushed up to name.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender. J. J. L. Lilly.—The seed of Spinach Beet can be procured through any seedsmen.

Catalogues received.—Dahlias, Bedding Plants, &c.—Mr. George Humphriss, Kingston Leazes, Gillingham, Newcastle-on-Tyne; Messrs. J. C. G. & Co., Denham and Co., 4 San Giovanni a Teduccio, Naples, Italy.—Stove and Greenhouse Plants, &c.—Messrs. E. D. Shuttleworth and Co., Albert Nurseries, Prossham Ry, London, S.E.—Flowering and Ornamental Shrubs, Perennials, Rock Plants, &c.—Mr. Thomas Hayes, Lake rose Nurseries, Rickwick, Cumberland.—New Roses and Florists' Flowers.—Messrs. Wm. Paul and Sons, Waltham Cross, Herts.

PANSIES! PANSIES!!—The following 12 grand varieties for 5s.: Betty Keble, Alice Russell, A. H. Murray, Elizabeth Patterson, David Keble, Jimmie Scott, Miss Hudson, Mrs. Archer, Alex Smith, Mrs. G. Thomas, Thomas Hasty, Lord Te. nyson.—A. BAILEY JUN., Fanny Grower, Sudburland.

PANSIES! PANSIES!!—I offer following 14 exhibition varieties, 3s. 6d.: Mrs. Freeland, D. Sturte, Maggie A. Scott, Eliza Paterson, A. Agnes F., Borrowmoor Lass or Gowrie, Lou. McIlcaia, Edith Brown, Duchess F. or Isaac, My Lady, Nell Gillis, George Cromb, Mrs. L. Canney, Robert Stobbs.—A. BAILEY JUN., Fanny Grower, Sudburland.

VIOLAS! VIOLAS!!—The following 12 grand varieties: Countess of Hopington, Lord Elcho, Miss Gifford, Mrs. Bissman, Mrs. Colman, Blanche Goud, Miss Goud, Lord Derby, Croft House, Abercrombie Beauty, Mrs. G. G. G., Mrs. G. G. G., Mrs. G. G. G.—A. BAILEY JUN., Fanny Grower, Sudburland.

ROSES.

ROSE NOTES.

I THINK it worth recording that several bunches of White Banksia Roses were cut from a plant growing on the front of a gentleman's residence on the last day of March just past. The aspect is south, and the situation a sheltered one. The plant, I may mention, is rather an old one, reaching to a height of about 20 feet. This is the earliest date on which I have known Roses of any kind to be in flower out-of-doors, and is evidence of the earliness of the season so far. Associated with the same plant is one of Gloire de Dijon, with the flower-buds well advanced. Perhaps I ought to mention that I write from the West of England.

TEA ROSE ADAM.—I am free to admit that there have been many beautiful new Tea-scented Roses introduced within the last few years; but, except that they differ somewhat in colour, and are more hardy, there is not one that surpasses the exquisite beauty of the Rose I have placed at the head of this note, though it is an old one. I believe it was introduced from France about the year 1838, so there are few older kinds now in cultivation. In catalogues the colour is described as salmon-rose, but in some charming blooms that I saw in the conservatory at Monty's Court, near Taunton, a few days ago, I could not find any trace of salmon colour, but a rich tone of soft rose pervaded the whole of the bloom, except at the base of the petals. I do not know when I have seen such a combination of sweetness and delicate colouring in any flower. It is unfortunate that it is not hardy enough for outdoor culture, but as a moderate climber—as the plant is grown to which I refer—it does exceedingly well under glass, and is nearly always in flower. I have, however, seen this Rose at different times during the past five years, and it has never been without either buds or expanded blooms.

MARECHAL NIEL IN THE OPEN AIR.—I recently stated that, so far as I knew, this Rose was not subject to canker when grown out-of-doors. I find, however, that such is not the case, as in the garden alluded to in the preceding paragraph there is a plant on the south front of the house that is as near dead as possible, owing to canker having attacked the stem just under the surface. The plant is about ten years old, and five years ago was in a fairly vigorous condition, but since then it has been gradually dying.

CLIMBING NIPHEROS.—It may not be generally known that this Rose submits to being cut down in the same way as Marechal Niel is treated as soon as the first lot of flowers fade; having tried it, I speak from experience. By cutting back the last year's growth now one loses the second crop of flowers; but as these come in when white Roses can be obtained from the open their loss is more than made up for by the increase in the size and number of blooms obtained early the following year from the young wood, which results from the cutting-down system.

NEWLY PLANTED ROSES.—Up to the time of writing the season has not been favourable for late planted Roses. The want of rain is much felt, as the growth shows signs of shrivelling, and nothing short of a good root watering and a thick mulch of manure laid on the surface directly after will save them. A good syringing two or three times a day would also help them immensely while the dry weather lasts. The Rose-maggot will no doubt be in evidence earlier than usual according to the season. A good look out must therefore be kept for them, so as to destroy them before they do any harm.

J. C. C.

Rose William Allen Richardson.—This Rose was introduced about fourteen years ago, and became very popular on account of its charming and unique colour. In this respect it is one of the most distinct Roses we have. Unfortunately, it has two or three peculiarities that are more generally associated with Marechal Niel; I allude to canker, wartiness, and very erratic and uncertain growth. One may plant either of these varieties, say six of each, and although they are all treated alike and are of equal strength and quality when planted, a couple of seasons will probably see two-thirds of them grown into grand objects, while the remaining third will scarcely have improved since they were transplanted; indeed, some may be worse than when first planted. This is a peculiar characteristic in both of these grand Roses, and one which I cannot account for in any way, as I have found the same results occur among plants that were propagated from the same shoot and upon stocks of similar strength and quality. Both varieties are also much subject to canker, and this annoying disease naturally attacks the strongest plants with extra severity. The complaint which I will call "wartiness," for want of a better name, seems to me to also be a species of canker, but this occurs at many places upon the plant, and not at the junction of stock and Rose, as is usually the case with the ordinary form of canker. William Allen Richardson also varies very much in colour, the flowers sometimes being of a very deep orange-yellow, while at others they may be almost, and even quite, pure-white; other flowers will consist of these two colours blended more or less with one another. In either case it is a most useful Rose for button-holes. It is necessary to call attention to this variation of colour, as many purchasers have complained prematurely of having been supplied with an inferior or spurious variety. I have noticed these different shades of colour upon the same plant and even upon the same truss. This is the finest deep orange-coloured climbing Rose we have, and deserves to be quite as extensively planted as Marechal Niel.—R.

A cankered Marechal Niel Rose in a greenhouse.—I had a Marechal Niel Rose to which I was attached from association. It became badly cankered and looked like dying. I divided a flower-pot and put the two parts round the canker last summer, filling the pot with earth and moss to prevent the soil, which is loose and sandy here, from washing away. Round the canker I bound a piece of a cloth left by

the painters, and I watered the pot carefully every day. The Rose revived, and had a few small flowers last autumn. This spring it started into vigorous growth, and the gardener and I found the pot full of healthy roots which were growing downward to the ground. He was unwilling to do it, but under my direction about five weeks ago he divided the stem, which parted at the canker, and by digging away the soil beneath we carefully lowered the new roots with the main part of the new growth into the ground, filling the hole with fresh soil. The plant has in no way suffered, and now has quite fifty large well formed flower-buds on it. The stem removed, with a small piece of new root, was potted, and has not flagged, but is growing well; and had not the gardener been afraid to try leaving the head on, I believe it also would have flowered. The whole plant was brought here eight years ago last November, having to my knowledge been flowering for several years previously.—M. F.

3524.—ROSES FROM CUTTINGS.—Your enquiry covers a good deal of ground, and would require a whole page to answer fully. Regarding the right time to put in the cuttings, that depends on when you can get them. If you have Roses growing in a warm house you may be able to get cuttings now. If so, secure the hardest of the young growths and make them into cuttings, each cutting to have three eyes, and one, if not two, leaves left upon it; then insert them in pots of sandy soil, and place them on bottom-heat. If the latter is not available, you had better wait another month before taking the cuttings; then place the pots in a small frame or a box in a warm corner of the greenhouse. If a box is used, a square of glass must be had for a covering to exclude the air. With regard to the kinds of Roses that may be raised from cuttings, there are some—the Old Cabbage and Pink Moss Roses—that are not readily increased in this way. Most of the Hybrid Perpetuals and Teas, as well as the Noisettes, are not difficult to propagate in this way. Supposing all these are available, and you have only the convenience of a cold frame in which to place the cuttings, you had better wait until the beginning of August before you make a start. Even then it will pay you to make up a hot-bed for the frame, and plunge the pots to their rims in a bed of soil from 4 inches to 6 inches deep. Treated in this way, the cuttings will form roots in about two months. Another plan is to mix up a good lot of sand with the soil on a border facing east or west, then put on the frame, and dibble the cuttings firmly in the soil. Another lot of cuttings from the H.P.'s may be put in the open ground the first week in October, a fair proportion of which may be expected to grow. If you put the cuttings under glass at any time before October, you must keep them shaded, and in bright weather damp them in an afternoon with a syringe, and be careful not to let the soil below the surface get dry, or the cuttings will surely die. Cuttings put in in October should be stouter and longer than those taken earlier, and not more than one or two eyes left above the soil, and in every case press the earth firmly about their bases.—J. C. C.

GARDEN WORK.

Conservatory.

We shall never have a busier time than the present. Many things require potting on, and must have attention without delay, or they will suffer. A group of Fuchsias just expanding their buds have a charmingly fresh look about them. Polargiums of the old-fashioned type are very effective, as are also the double and single Zonalis. Plants of the latter intended for blooming in winter should have the leaders pinched to make them bushy, and be potted on as more room is required. Large specimens will require a little training, but use as few stakes as possible, and have them small and not too conspicuous in colour. Bamboo canes are capital for training plants, and are cheap and lasting. Azaleas past their best clear of dead and faded blooms, and place in a warm, shady house to make wood. If perfectly clean they will do in a warm vinery; but if there is any suspicion of thrips, keep them out of the vinery. Cyclamens out of bloom move to a cold pit to complete and ripen growth. Young Cyclamens coming on will require warmth to encourage growth. It requires good culture to grow Cyclamens from seed to the blooming stage in one season. Most of the large growers sow their Cyclamen seeds almost as soon as ripe, and give the plants more time to grow from good strains of Cinerarias and Chinese Primulas. Old plants of both, if no longer effective, may be thrown out. Look closely after insects and check their approach by the use of insecticides. I am always averse to fumigation when the house is gay with flowers, as the petals droop so much when the house is heavily smoked. Heliotropes planted out to the border, either grown as bushes or trained up a wall or pillar, are very fragrant, and useful for outding. Remove all Camellias, as the flowers are not required now. Double Wallflowers of good strains are nice things for the conservatory. I saw a group of these in a friend's conservatory a few days ago, and very sweet they were. The seeds should be sown next month and the seedlings pricked off in the beeder outside to be potted up in September, and kept in a cool pit to come on gently during winter. Hard-wooded plants, such as Heaths, Azaleas, and New Holland plants generally, may be potted off if they require it. Large specimens in good condition may go several years without a shift, especially if helped with a little stimulant during the growing and flowering seasons. See that cilmbers are properly thinned and trained; things soon get into a hopeless tangle if neglected. Give copious waterings to plants in bedders, such as Roses, &c.

Stove.

Growth is very rapid now, and the bright tints of leafage and blossom are well brought out under the very thin shade which it has been necessary to use during the late bright weather. Repot young plants into larger pots, but it is always advisable to leave a considerable number of healthy young plants in 5-inch pots for table decoration and general furnishing. It is always necessary, where much furnishing is done, to have young plants and seedlings should be raised in quantity every season. Five-inch pots filled with Lycopodiums, Panolom variegatum, Tradescantia vittata, and other plants of ornamental character in a small state, should be filled every spring, as for this purpose old plants are of no use. Tuberoses may be brought forth in large quantities. It is always desirable to grow the finest flowers to be obtained when the plants are kept on in heat; but Tuberoses will flower in cool greenhouses. They will come later, of course, but it is an advantage to spread the blooming time over the season as much as possible. Shift on young stock of Bonvardias, and continue to strike cuttings of Polanthes. Cuttings of the soft shoots of Gaedelia, Ixoras, &c., will root now in a brisk bottom-heat.

The Orchard-house.

The culture of fruit-trees in pots is very interesting, and its details are not difficult to master. One must not recommend it for the supply of a large family, but for the amateur who likes a succession of fruits, but not in large quantities, the pot system of culture will suit admirably. I have been told the Messrs. Rivers sell thousands of trees annually, and the purchasers are chiefly amateurs. Given a light, airy house, with just pipes enough to keep out frost, though there is no reason why Peaches in pots should not be forced. Where the orchard-house system is once started it is always desirable to have a warm-house as well as a cool one. In the warm-house, early Peaches, Figs, and Grapes may be grown; and in the late house, late Peaches, Figs, and Cherries. One of the advantages attached to the growing of fruit-trees in pots is this—the houses may be cleared of the trees in autumn, and filled with Chrysanthemums, and as now it is not uncommon for an amateur to grow some hundreds of these the difficulty of housing them would be solved if one combined the culture of fruit with Chrysanthemums. Tomatoes will do treated in the same way. Planted early in spring, the Tomatoes will be pretty well over by October, and the Chrysanthemums ready to be taken in.

Mushroom-beds in Cellars.

It is sometimes thought that manure piled in the basement of a house is not necessarily bad and unhealthy; but if any bad smell arises it will be due to neglect. Mix one-fourth of loamy soil with the manure, turn and blend it well, make up the beds in the form of edges on the floor, and cover with a little loose soil to absorb any ammonia which may arise during the process of fermentation. Spaw when the temperature is steady at 85 degs. or so. Add 1/2 inches of soil when the spaw is working freely, and cover with long old hay or old mats will do. Covering keeps the moisture in the beds. Beds in hearing must have moisture; liquid manure will be beneficial. Atmospheric moisture must be kept up by flooding paths and damping walls.

Cold Frames.

Where there is much bedding out temporary shelter may be improvised now with the aid of rough boards and stout canvas.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than as here indicated with equally good results.

be moved to the temporary pits, and the frames be filled up again from the houses. Cucumber and Melon seeds should be sown now to have young plants ready to set out when the bedding plants are removed.

Window Gardening.

Stand Spiraea in pans of water, so they are so difficult to keep moist. When Azaleas have done flowering, pick off dead flowers and seeds, examine drainage, and see if the plants require repotting. If potting is required do it at once, and then keep the plants in the warm part of the room till the growth is made, and getting a bit firm. This will take till July, and the plants may then go into the open air.

Outdoor Garden.

The sunshine is splendid, but if it continues the water-pot must be used freely, especially to newly-planted trees and shrubs; even newly laid down lawns must be watered if the Grass is to get established quickly for lawn-tennis or cricket, a watering of newly-out Grass will be beneficial on newly-laid turf, and mulching of some kind is absolutely necessary to all newly-planted trees. If small seeds are required to germinate quickly the ground should be watered before sowing, and after the seeds are sown and covered with fine soil shade of some kind must be improvised. It is a very rare occurrence to recommend shade for outdoor crops in April, but the sunshine this year is quite phenomenal. If it is necessary to transplant anything during this dry weather the plants must be well watered before removal, and be potted in the house and then mulched, and, if possible, shaded, the syring being used freely over the foliage. If proper precautions are taken planting may be done morning and evening without injury to anything. Cut all dead wood out of specimen Hollies, and shorten back long shoots where symmetry is essential. The proper time to prune all flowering shrubs is immediately after flowering, and the best way to keep them in condition is to do a little pruning annually. In most cases all that is required is to wood out the long, straggling branches, or to give room to the young shoots to come up. When flowering shrubs are pruned in winter the blossom-buds are out off; but if pruned after flowering there will be a good bloom every year. The night has sometimes been cold and frosty, but I have never seen the Bleeding Heart (Dielytras spectabilis) in better condition than it is at the present moment. Not a single flowering-shoot has been injured. Dry frosts are not nearly so injurious as when a frost follows a storm of cold rain or sleet. This is a very good lawn plant for a sheltered rosette. I have seen it very effective at several gardens lately. Solomon's Seal also is another useful subject, especially for partially shaded borders. Wonderfully bright are the masses of Hyacinths in beds and borders, not a flower damaged by wind or storm. There should be no difficulty now in thoroughly eradicating all weeds. Use the hoe freely.

Fruit Garden.

Fruit prospects, at the time of writing, are still satisfactory. There is so much blossom on the Plum-trees that a severe thinning will be an advantage. Pear-trees also are white over with blossom, and here, again, a severe thinning will be beneficial in every way. So long as the weather continues dry the low temperatures at night will do no much harm, and Peaches on south walls will, on dry, porous soils, require watering. If green-film appears on Peaches dust with Tobacco-powder immediately, and repeat occasionally so long as a fly remains. Peaches under glass will require a good deal of attention now in tying down young wood. There is frequently too much of this wood laid in. Only sufficient young shoots to form the bearing wood of next year are required. In thinning the crop a good deal of resolution is necessary, especially if the fruit are for sale, as small, badly-grown Peaches are worthless. Liquid manure freely to Peaches where the stoning is completed, but discontinue it now as soon as the fruit begins to put on colour. If Peaches are watered up to the time they are fully ripe the flavour will generally be spoiled. Peaches should not be hurried during the stoning period, but afterwards a night temperature of 60 degs. may be employed to push on the fruit if required very early. Early-forced Vines in pots will now be colouring their fruit, and more ventilation will be required; in fact, the house should not be altogether closed, as most good cultivators leave it wide open at night. In giving stimulants to Vines strong liquids should not be used too freely. I would rather mix whatever artificial is used with the top-dressing than run any risk of spoiling the colour, which is too liberal use of strong liquids will sometimes do. I have still seen late Strawberries in pots packed away under a north wall, but these will be started now in a cool pit.

Vegetable Garden.

Small seeds at the time of writing want rain. In sowing seeds now place them rather deeper in the ground. This refers to all seeds, such as Peas, Beans, Turnips, Beet, &c. When the seeds germinate they will soon force their way through the soil; but small seeds will not germinate in dry, hot, dusty soil. They should be laid in a little deeper, so to come into a moist soil. Liquid manure is not so much good. They require some knowledge of French cookery to be thoroughly appreciated; but, if wishing to give them a trial on early raised plants from seeds sown in small pots, three seeds in a pot, to be reduced to one when the strongest can be selected. Place the pots in the greenhouse or pit. Later crops can be planted in trenches like Celery, the seeds being planted at intervals of a foot or so all along the drills. The plants are tied up and blanched when large enough, or, say, by September. Hay bands are usually wrapped round the plants to keep them together, and prevent the soil getting into the hearts when the plants are earthed. Continue to prick off Celery till enough plants and a margin beyond have been secured. Shade and moisture are essential for rapid, clean growth. Turnips in good soil may be sown in rather larger quantities. I don't know a better variety for sowing now than the Early Milan, which is a kind of Strap-leaved Stone. Later on there is nothing better than Red Globe, or the Red American Stone. Get Potato-planting finished in the backward districts. Plant Marrow Peas in succession. The seeds are planted in rows to select from. Sow a row of dwarf French Beans on the north border. These are very often planted too thickly. Plant in single rows 2 1/2 feet to 3 feet apart, the Beans in lines 6 inches apart.

Work in the Town Garden.

The weather is still extremely dry, and newly-planted trees, shrubs, and other plants must be kept well watered at the root, or they will probably perish. Under present conditions nothing can make much growth. What we want now is a nice warm rain, and with genial weather afterwards things all round would come on apace. Seeds of hardy annuals and others go in the ground very easily now, but they cannot germinate until rain comes, and in the mean time they may be kept in a box in a water-pot to water artificially, and perhaps the best plan is to water the beds, lines, or patches well first, then sow the seed, cover with a little fine sifted soil, and finally with manure, old soaks, or the like. This will greatly check evaporation, so well as wadding off night frosts, so germination will soon take place, and then the covering must be gradually removed. In this way Lettuces and other small seeds will come up in a few days, and during a dry period much the best plan is to sow where the plants can remain, and merely thin the seedlings out. Seeds of hardy biennials and perennials, including Carnations, Sweet Williams, Wallflowers, and many others should be sown this month. This may be done in a well-prepared bed of fine soil out-of-doors; but if only a few plants are wanted, or the seed is particularly choice, it is, perhaps, better and safer to do so in good-sized boxes and place them in a cold frame, pricking them outside when sufficiently strong and the weather becomes milder. Carnations are among the best of two sorts, and there are nothing like seedlings for producing quantities of flowers for cutting, and, so that a batch should be raised wherever possible. I usually sow in boxes in a frame or cool-house, and prick the plants off into nursery-beds when about 1 1/2 inches high, finally planting them out where they are to flower in October, or, if the place is very smoky, pot them singly, water in frames, and plant out in the spring. Almost all of the large genus of Campanulas, too, are capital plants for town gardens, and C. as well as C. carpatensis, C. pyramidalis, C. turbinata, and C. alba are easily raised from seed, which should be sown now; but, being rather fine, it is best to do so in boxes under glass. Plants of C. pyramidalis alba form excellent ornaments for the conservatory, and those raised last year from seed should be transferred at once to 6-inch or 7-inch pots to flower. The varieties of C. perfoliata, but especially the double white, are grand for supplying cut flowers. These are increased by division, and should be potted in cool pits. Indoor plants, Ferns, Dracaenas, and other foliage plants ought to be given a little water. Keep them warm and close in a moist atmosphere for some time afterwards. Sow seeds of Chinese Primulas immediately. B. C. R.

THE COMING WEEK'S WORK

Extracts from a garden diary from April 22nd to April 29th.

Filled a frame covering a gentle hot-bed with cuttings of Alternanthera, Frestes, and Coluses. I still do a little carpet-bedding, and these bright-foliated plants are necessary for such work. Pricked off seedling Verbena, Stocks, Astors, Zinnias, Palox Drummondii, &c. Potted off spring-struck bedding plants in variety. Shall give them a start in heat, and afterwards harden off. Most of the autumn-put plants have been placed in cold frames to harden. When thoroughly hardened they should be sown in the beds. Commenced dibbling Peaches on walls, removing the forsights first. I always, when dibbling, have the Tobacco-powder distributor handy, and if a fly is seen a little powder is dusted there, and the same tree is visited again in three or four days, and more powder used. This is the best and cheapest way of clearing out insects. Planted out Lettuces and autumn Giant Cauliflower. I always plant a few of these in different aspects to insure succession. Cauliflowers in summer will do very well under a north wall if the soil is in good condition. Finished making new plantations of Violets, Marie Louise being largely grown for Ixora culture in winter. Shifted on Chrysanthemums. These are still in cold pits, and will not be placed outside altogether till May is somewhat advanced. Tied and dressed Cucumbers. By dressed is meant pinched off tendrils which are produced freely on vigorous plants. Every year's experience adds to the conviction I feel that crowding Cucumber plants under glass will not pay. Those plants set out 6 feet apart soon set, and when plenty of space is allowed, the plants seem to increase in vigour in proportion. Frequent top-dressings of old turf and manure are very beneficial. Maintain a night temperature of 65 degs. to 70 degs., with abundance of moisture in the atmosphere, and also keeping the roots moist. Cucumbers grow and thrive amazingly. A light shade is necessary now. Cucumbers do very well under a permanent shade of wire and whitening, or size and flour will do. I always cut the fruits as soon they are large enough to use. Cucumbers may be kept quite fresh with the ends in water in a cool place for a week, though I never keep them so long. Tied down and stopped Vines in a late house. Only one bunch is left on each lateral, and where the bunches are large, some of these will be cut away when thinning, as overcropping must be guarded against. Stopped Vines in three kept up in Tomato-houses. A little strength in the vines gives on a full compass of the situation, especially in regard to ventilation. Tomatoes in a house badly ventilated will come to grief before the summer is half over. Sowed more Marrow Peas, and made a sowing of Turnips, Spinach, and Beet. The Spinach Beet is grown to a limited extent. It makes a useful substitute for Spinach, and it is sometimes used for stuffing salt meats. Increased the plantation of Good King Henry or Mercury by removing the young offsets and planting in rows 12 inches apart, and a foot apart in the rows, matching with manure. Mulched plantations of Strawberries with long manure, and gave a sowing of house sewage. Shifted on Zoni, Pelargoniums intended for winter blooming. Rearranged conservatory. Thinned and trained creepers. Shifted a number of Campanula pyramidalis into 8-inch pots. These will make good specimens for late blooming.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables to draw. The drawings so made will be engraved in the best manner, and will appear in due course in Gardening Illustrated.

INDOOR PLANTS.

LILIES IN POTS.

I AM afraid that amateur gardeners who have the convenience of a small greenhouse do not grow Lilies so much as they ought to do, and especially the varieties of *L. speciosum*, or *lancifolium*, as it is commonly termed. It is easy to cultivate this type, and the return they make, if well managed, in every respect satisfactory. Of *L. speciosum* we have several varieties—viz., *album*, white; *punctatum*, white, flushed with rose, a somewhat scarce but very pleasant form; *roseum*, white, spotted with rose; and *rubrum*, white, heavily flushed and spotted with crimson. The two last can scarcely be termed distinct, as it appears to be the practice to mark all the dark-coloured varieties found among the roseums, and send them to this country under the name of *rubrum*. The variety *album* is a singularly chaste and beautiful Lily. *L. speciosum* Krætzeri (here figured), white, is a very fine form. I think that the white *lancifolium* and *L. longiflorum* are the two most charming Lilies an amateur can cultivate; the last for early blooming, the former for late blooming, with the fragrant *L. auratum* to come between them.

are helped by occasionally dusting the surface with Clay's Fertiliser. Some adopt the practice of placing the bulb in the first instance in the smallest possible pot, and then to shift into larger pots as the plants progress in size, and the flower-buds appear, and then no further shifts should be given.

THE soil I use is made up of some rich yellow fibry loam, leaf-mould, peat, Cocoa-nut fibre, sand, and some decomposed manure, taking care that the latter contains no insects likely to be injurious to the bulbs. The presence of grubs in the pots will often destroy a good bulb or two. My selection, it may be remarked, is a somewhat limited one. It is so, but it can be extended with advantage. Add *Lilium Harrisii* and the early-flowering varieties of *L. Thunbergianum*, of which there are a few. They are dwarf in habit, and produce extremely showy, handsome flowers on bold trusses. Other choice kinds can also be added as it is desired to extend the collection, but those named will be found ample to commence with. Notwithstanding so much has been written in praise of this culture of Lilies in pots, their cultivation in this form extends but slowly. If anyone wishes conclusive evidence on this point, let him take

pots in a brisk bottom-heat and keep moist, and close shaded from bright sun till rooted. Under suitable conditions every cutting will root in a few days. The softest cuttings will root the best.—E. H.

— Heliotrope cuttings root as freely as almost anything known to garden culture. I have propagated a large number during the early months of the present year, and they are now well-rooted plants. They should be taken off and cut into short lengths, and be planted in fine sandy soil. They will form roots in a week or so in a hot-bed, and when rooted they grow very rapidly in a little bottom-heat, and should be planted out in boxes almost as soon as rooted.—J. D. E.

3530.—Garden frames.—There is no difficulty in heating the pit, either with a flue or a small hot-water apparatus, and at the same time you may use stable-manure to furnish bottom-heat for Melons in the summer. The pit should be 2 feet 6 inches deep below the ground line, and the front wall should be 18 inches high from the same level. This will give you a depth of 3 feet for manure and soil, and leave a space of 12 inches along the front for a flow and return hot-water pipes. If 3-inch pipes are used they will give all the heat you want. Cinerarias and Calceolaries will do very well if they stand on a bed of soil during the winter, but "Geraniums" and Primulas require drier quarters. For this reason one half of the pit should be emptied of the manure and soil at the commencement of winter, and a temporary bench or platform should be erected 1 foot from the glass in front for them to stand upon. You will increase the value of the pit if you put in two or three ventilators in the front and back walls, the bottom of the openings being on a level with the ground, and if the ventilators are 4 inches deep and 18 inches long in the clear you will find them wonderfully useful in expelling damp in winter. A small "Independent" boiler fixed at one end of the pit is what you require. If you have the lights 3 feet wide instead of 4 feet you will find them more manageable and less liable to get out of repair than wider ones.—J. C. C.

3522.—A lean to greenhouse.—Yes, such a structure would be very suitable for Tomatoes. Strong, well-hardened plants may be put out at any time now. Keep them rather dry at first, and afterwards ventilate freely. Perfection is a fine large-fruited kind, of strong growth, and suitable for a lofty house; Blackwood Park is very prolific, and Field Gem is at once highly productive and of delicious flavour. Plant them out in a well-drained bed of sandy loam, or grow them in good-sized boxes.—B. C. R.

3495.—Culture of Justicia and Eupatorium.—These are not difficult to manage. The Justicia is a stove plant, and should be grown in a warm-house till end of June, and then moved out to a pit to ripen growth, to be placed in heat again end of September or beginning of October. It may have the leading shoots pinched once to induce a bushy habit, but should not be pinched after end of May. The Eupateriums are greenhouse plants, but they thrive and grow freely in a warm house or pit till some progress has been made. I have always found the planting-out system to suit these plants better than growing them all through the season in pots; they make more growth and flower better. May be planted out on a sunny border early in June, watered freely in dry weather, strong shoots pinched once or twice to induce a bushy habit, and potted carefully up in September—a firm potting. Stand under a north wall for a few days till the roots begin to work.—E. H.

3509.—A lean to greenhouse.—Yes, you ought to be able to do Chrysanthemums well in such a structure, the latest kinds, perhaps, excepted. Obtain young plants or strong-rooted cuttings at once, pot them into 3-inch pots, keeping them rather close for a week or two until established, when free ventilation must be the rule, and as soon as the latest kinds are getting full of roots shift them in 5-inch sizes (large 4's), and when "getting hold" a little, remove them to the open air, standing them on ashes in a sheltered but sunny position. About the middle of June shift them on into 8-inch or 9-inch pots to flower, still keeping outdoors, and house

Lilium speciosum var. *Krætzeri*.

Yet many amateurs are found complaining that they cannot grow these charming Lilies in a satisfactory manner; that they fail to grow, the

BULB ROTS, or they make a good growth and fail to flower, and they are killed in the winter. There are difficulties to be overcome, but they can be overcome by diligent attention and painstaking. My practice is to flower the Lilies in an ordinary greenhouse, and when they have done flowering leave them in the greenhouse to mature their growth; then cut away a portion of it in early autumn, and place the pots in a cold frame for the winter, covering them up with leaves and Cocoa-nut-fibre, when the frost set in. It is during the winter that many plants are killed for want of adequate protection through lack of house room; in some instances frequently, it is to be feared, from lack of accommodation. In spring, just as the growth commences, I carefully repot, taking care not to overdo this, and potting sufficiently deep, so that a little fresh soil could be added when the roots thrown out at the base of the flower-stalk commence to form. When they have made a growth of 6 inches, the plants are carried to the greenhouse, and encouraged to make a vigorous growth. This is a simple, but in my own case successful, routine of practice. I do not repot but when the plants are fully established they

the many flower shows, in the schedules of which prizes are offered for Lilies in pots. How seldom does a respectable collection put in appearance at the season of the year when there should be no difficulty in having a group of four or six varieties! They are always objects of great interest at a flower show when presented in respectable form. R.

3499.—Eucharis bulbs.—It is not uncommon for Eucharis bulbs which have been starved to throw up flower-spikes before leaves are made, and the smallness of the flowers points their to improper treatment. This bulb, under the usual treatment, is an evergreen.—E. H.

3501.—Rooting cuttings.—There is no secret about rooting cuttings of Heliotrope. Fill a box with light sandy potting-mould, take off your cuttings close below a joint, selecting about 8 inches of the terminal shoots, strip off the lower leaves to the middle and insert firmly about 2 inches apart in rows, then thoroughly moisten the earth with a spout between the rows of cuttings and stand on a shelf near the light. At this season you ought to root the whole without difficulty.—A. G. BUTLER.

—The surest way of rooting cuttings of Heliotrope is to take off the soft ends of the shoots, trim off the bottom leaves, and divide the pots of light sandy soil, and plunge the

again from the middle to the end of September, according to your locality and the season. If bushy plants rather than large flowers are desired, nip out the point of each plant as soon as they begin to grow, in the small pots, and take up three to five stems instead of one, and if very dwarf plants are preferred, cut them down to 6 inches of stem at the end of May, giving the last shift as soon as the young shoots are an inch or two long. A few suitable kinds would be, for early flowering: Mme. C. Desgrange (white), G. Wernig (primrose), and Mrs. Hawkins (deep golden-yellow), M. G. Grunerwald (pink, very fine), Roi des Pêcheurs, and W. Holmea (crimson). To succeed these you may grow Elaine and Avalanche (pure-white), Sunflower and Mr. Gaman, or W. H. Lincoln (yellow), E. Molyneux and Cesare Coeta (crimson), Mrs. L. Jamieson and Bonis d'Or (bronze), Mme. de Sevin and Red Audigier (rosy-purple). These are all Japanese kinds. If you have room for any more add Mrs. G. Rundle (white), G. Glenn (primrose), Mrs. Dixon (golden), Lady Dorothy (bronz-apricot), and Venus (lilac-pink), all incurved; also Chev. Donage and Elsie (golden-yellow), Cullingfordi (scarlet), Christine (peach), and King of Crimsons, or Julie Lagrèze (crimson). It will be a great advantage if you can fix a blind of some thick, warm material, such as Frigi Domo, on a roller to run down over the glass on frosty nights in the autumn.—B. C. R.

3512.—Plants for market.—*Ficus elastica* is propagated by means of cuttings, *Aspidistra lurida* by division, and *Acacia lophantha* is raised from seed. The first requires plenty of heat and moisture and a light, peaty loam to grow in; the *Aspidistra* will grow almost anyhow, but faster in a moderate warmth, of course, and *Acacia lophantha* needs warm greenhouse treatment. *Adiantum cuneatum* is grown almost exclusively for cutting; it may be increased by either division or seeds, but seedlings make the best plants. The best Regal Pelargoniums are *Triomphe de St. Mandé*, Ed. Perkins, Maid of Kent, and Mme. Thibaut; but the best kinds for forcing are found among the French varieties. The old *Veauvine* and West Brighton Oem (scarlet), and H. Jacoby (crimson) flower earlier and more freely than most of the larger kinds.—B. C. R.

3520.—Small greenhouses.—Cucumbers alone will not pay for fuel and attention in winter; but the houses may be used for forcing flowers, such as Lily of the Valley, &c., and if carried out with judgment there is usually a profit left. French Beans and Mushrooms may be combined with the Cucumbers, if there is room.—E. H.

—If you have a good market, Cucumbers may fairly well during winter—that is, if properly grown, so as to ensure a good crop. In and near London they are most profitable during March, April, and May, or in "the season." To do Cucumbers justice, however, it ought to have the houses to themselves, or nearly so, and the only other plants that can be grown under glass in this case to any advantage are Ferns, Palm, and *Lycopodium*.—B. C. R.

3453.—Hot-bed making.—If for a three-light frame, get together about six cartloads of good stable-manure which has been once turned over, mix with them one load of undecayed leaves, or the leaves may be put on in layers through the bed, about 1 foot thick when loose. Tramp the bed only moderately; this is most important. Set your frame on top of heap with the lights on, and in about ten days to a fortnight, riddle some nice loamy soil, and place in small hillscks—one for every Melon-plant—the light would take four comfortably. Plant out your Melon-plants when fit on the top of these hillscks, and from time to time (as they require it, add more soil of good quality.

TREES AND SHRUBS.

CHOICE FLOWERING TREES AND SHRUBS.

CHINESE AKEBIA.

This is an elegant, twining evergreen shrub (see illustration) from China, usually grown in greenhouses, but hardy enough for the open air in the southern and west-coast counties of this country. It is a charming plant for covering a

Flowering-branch of Chinese Akebia (*A. quinata*).

trellis, pergola, wall buttress, or any place where, in case of very cold winters, it can have protection, if needed. In some mild localities it does not need this even, but rambles over shrubs like a Traveller's Joy. It is best to let it run over an Evergreen, as then it is better protected against cold winds, which injure its flowers. It has long, slender shoots, foliage with five leaflets, and its flowers are of two kinds—large and small, produced in drooping spikes. They are of a deep claret-purple and fragrant, produced in February in greenhouses, but later in the open air. It is propagated by cuttings and it grows to a height of about 12 feet. G.

3523.—Layering Rhododendrons.—You may layer these at any time, but the present is perhaps as suitable as any in the whole year. You have only to bring down the young branches on to the ground and cover them with 6 inches of soil, and they will be sufficiently rooted in two years to plant out where they are to remain. Only the common ponticum variety will do any good under Beech-trees, and not even these unless the soil is suitable, and deep as well. I certainly should not think of making a soil in such a position if the staple is not of a promising character.—J. C. C.

3482.—A high hedge.—If the hedge is to form the outer or boundary fence, I think Quick or Privet, or a mixture of the two, will be as suitable as anything that will grow so quickly. It will be necessary to cut the plants

in a double row, about 9 inches or a foot apart, and let the hedge have plenty of room if it is not to be thin at the bottom when it has reached the height of 8 feet or 10 feet. It will, after a few years, require careful clipping, and must be kept free from weeds from the first. Holly would make a handsome hedge, but grows slowly. Of Yew it is safe to put in larger plants, but it is too poisonous to cattle to be desirable for an outer fence. Laurel, when clipped into a stiff form, is ugly, and is liable to die during hard frost. Of the merits of the *Myrobella Plum* I cannot speak.—E. E.

Fyrus japonica.—There are several varieties of this fine spreading shrub, but the most beautiful is *P. cardinalis*, which is in the nursery of Mr. Anthony Waterer, at Knapp-hill. The common type is peculiar in many gardens, but the variety *cardinalis* has much larger, better shaped, and most brilliant flowers, intense crimson, conspicuously bright and showy. It blooms with great freedom, and is a variety thoroughly worth growing in every garden where space can be found for a *Fyrus*. Many of the forms of *P. japonica* are too pale in colour to be effective; they are washed out, so to speak. *P. Manley* is a good kind, the branches quite wreathed with the orange-scarlet tinted flowers, which are set closely on the slender branches. It is not necessary to grow *P. japonica* against a wall. It makes a lovely bush, a mass of scarlet flowers in April.—C. T.

Trimming Ivy.—Now is the time to clip or trim Ivy on walls or buildings, as it will soon be making its growth, and instead of being bare and shabby for weeks, as would have been the case if the work had been carried out before, the surface will quickly become re-clothed with new leaves. If the walls are low and can be got at easily, I find that the best implement is a scythe, which soon shaves the old foliage off close, and a sharp hook is also very useful. In places the shears must be used where a blow cannot be struck, as in angles and corners or under eaves. If Ivy is looked after and thus treated annually, it presents a fresh appearance all the year through and is kept close to the walls, instead of jutting irregularly out or becoming detached from its surface. In cases where Ivy has been neglected it may with safety be at once cut in, and if there is any rubbish amongst it, this may be got rid of by giving it a good brush over with a Birch broom, driving or using it upwards so as not to break the Ivy away from its support.—D.

3502.—Bulbs after flowering.—There are very often left in the beds altogether, especially Crocuses, Snowdrops, and Scillas. Aconites do better on some shady shelving bank, when they can be left undisturbed till they spread out into a broad mass. They are then really effective. If the beds are required for summer flowers, Hyacinths, Tulips, and Double Daffodils should be lifted with as much earth as will cling to them, and be laid in some where till the bulbs are ripe, and then sorted and placed in drawers till September or October, when they can be again planted. I think Daffodils should be planted early to give them a chance of flowering well.—E. H.

—All the spring-flowering bulbs, such as Crocuses, Tulips, Hyacinths, Narcissus, Snowdrops, Winter Aconites, &c., should be left where they are until the leaves decay, and if it is intended to plant them somewhere else that is the best time to lift them, and they may either be planted at once or kept in a dry place until the time that they show signs of starting into growth. It is better not to replant them annually, except the Hyacinths and Tulips, which may with advantage be taken out of the ground annually, and be replanted again in September. All the others may be left in the ground for a number of years.—J. D. E.

3453.—Moss on a lawn.—Without any delay tear up the Moss with a rake, or if your lawn is large enough use a small horse-harrow. At first it looks altogether destroyed, but do not despair. Then spread a compost of lime and good soil (lime, one to four of earth) about six or seven cartloads to the acre; then sow renovating G. a-seeds, one and a half bushels to the acre, roll well, and keep down (worn areas—

CHRYSANTHEMUMS,

CHRYSANTHEMUMS AGAINST A SOUTH WALL.

3515.—The best kinds for growing against a wall outside are those of the Reflexed section, which, owing to the natural imbricated form of their florets, do not retain water from rains or heavy dews amongst the petals like those of the incurved section. As long as the blooms can be kept tolerably dry in the centre, there is not so much danger of their suffering from frost and damp as when they are constantly wet. The large-blomed kinds of Incurved, such as Queen of England, for example, are the least desirable. Pompona and single-flowered varieties are deserving of attention, owing to the freedom in which their flowers are produced. Below I give a list of suitable sorts, attaching the colour of each as a guide in planting. The best kind of plants are those that flowered in pots last season. These are better than young ones from cuttings of the current year, owing to the extra number of shoots produced at the base, and thus are better furnished with branches to begin with. If these old roots are not available, procure at once some plants struck early during the present year; top the leading shoot to induce side branches to form near the base to furnish the wall right from the bottom. If old plants are available, remove part of the soil from the roots and plant them close to the wall at a distance of 3 feet apart. If the soil is fairly good, add some manure. Between each two large-flowered varietal plant one Pompona or single kind, which will cover the bottom part of the wall. Tread the soil firmly about the plants, and when they are growing freely supply them liberally with water. If the plants were of good size the previous year they will start into growth with many shoots. Select six of the strongest on each plant, removing all the others except from the Pompons, which may have eight growths. When the branches are long enough, spread them out thinly and secure them to the wall either with a wire run along the front of the shoots or by the aid of shreds and nails. Toward the end of May the shoots will each make its first natural break; this is caused by the formation of a flower-bud at the point of each. Select two of the strongest shoots on each original stem, or more if space will allow. It is not a good plan to overcrowd them. After a hot day thoroughly syringe the plants; this greatly assists in keeping the foliage clean and in a healthy condition. Should the weather be hot and dry during the summer, a mulching of manure, 2 inches thick, spread over the surface 1 foot away from the stem of the plant will not only be a saving in labour in watering, but will keep the roots cool and moist, which is all in favour of a successful growth. If some temporary protection can be provided, such as banging tiffany in front of the plants nightly when the blooms commence to unfold their florets, the frost will not injure the flowers nearly so much, and the blossoming period will be prolonged. In some seasons it is possible to have really good and fresh bloom as late as December 10th. Reflexed Japanese: Avalanche (white), Dr. Maury (white, tinted with rose), Edwin Molyneux (crimson and gold), Etoile de Lyon (deep lilac-rose), Fair Maid of Guernsey (white), Sunflower (golden-yellow), Maiden's Blush (blush), Mme. de Sevin (rosy-amaranth), Peter the Great (tomato-yellow), Val d'Andorre (red, shaded orange), Source d'Or (orange and gold), gloriosum (lilac-yellow, fluted florets). Reflexed: Amy Furse (lilac-blush), Chevalier Domago (bright-gold), Christine (peach), Mrs. Horril (lemon-yellow), Golden Christine (golden-hued), Cullingfordi (scarlet-crimson), Mrs. Forsyth (creamy-white), and Phideas (rosy-blush). Pompons: Black Douglas (dark maroon-red), President (deep rosy-carmine), White Trevena (white), Ronanite (silvery-blush), Fanny (maroon-red), Lizzy Holmes (bronze), St. Michael (yellow). Single flowered varieties: Mrs. Langtry (pale-pink), Jane (white), Mrs. Le Mout (amaranth), Mrs. J. Willa (white, suffused pink), OriGanne (soft reddish-brown), White Perfection (white), Florence (white, shaded rose). E. M.

time of year they will not do any harm. If the ants' nests are not too near the roots of any trees or plants the best way to destroy them is to open the nests and pour in boiling water; if they are not situated where this plan can be carried out they can be trapped, but this is very slow work. Pieces of string, lath, or anything else which is more convenient should be soaked in treacle and placed in their runs, and when covered with insects dipped in boiling water. A flower-pot turned upside down over the nest, with the hole at the bottom closed, and lightly fitted with Raspberry-leaves, has been found very useful, the ants removing into it if the ground round the nest be kept wet. Some persons poison the ants with treacle and arsenic; but poison is always more or less dangerous.—G. S. S.

FERNS.

MAIDEN-HAIR FERNS FOR CUTTING.

The idea seems to have crept into the minds of nearly everyone growing flowers for room decoration that some Maiden-hair Fern is necessary for mixing with them. I, too, love the greenery when mixed with flowers, but I do object to the use of Fern with some things. A Rose, for instance, looks far better when backed by its own green leaves. A Carnation or Clove looks certainly best arranged with its own leaves. But Fern fronds we must have, and the fronds of many Adiantums are peculiarly well adapted for this purpose. Our market growers have decided that *A. cuneatum* is the variety they will grow and will supply no other, so that this species has become the only accredited one worth attention for this purpose. In these notes I will describe a few kinds which can be grown for cutting, and which will at the same time give a greater variety and add a greater interest to the appearance of the house in which they are grown. I would advise my readers to grow a variety of taller-growing kinds; their fronds will be found ever welcome for cutting. These plants are all very easily grown. One of the chief items of success is good drainage, for without this no plant can long remain a pleasure to anyone; good soil, careful potting, and a plentiful supply of water to the roots, with an

shoulder sprays and wreaths, and they last a long time without fading. It will thrive well in the cool-house fernery, being a native of New Zealand. *A. cuneatum*: In spite of what I have said of this kind, I must on no account omit it from the most desirable kinds. The rich bright green of its fronds and the jet-black stripes render it very charming. Nothing can excel its beautiful fronds when used for bouquets and button-hole flowers, and that, too, in the winter months. It thrives best in moderate warmth. It is widely spread throughout Brazil. *A. excisum* and its variety are both very handsome plants, partaking somewhat of the characters of *A. cuneatum* and *A. concinnum*. The latter plant, however, is excluded from this enumeration. The fronds of *A. excisum* are three or four times divided and from a foot to 18 inches in length. The variety makes beautiful tassels some 3 inches long or more, and the fronds are very beautiful when cut for mixing with flowers for the table. It requires stove heat, and comes from Chill. *A. formosum*, a very handsome kind, as its name implies, grows to some 3 feet in height, but when the fronds are about half that size they are exceedingly useful for mixing with cut flowers, where their bright green pinnules and jet-black stripes are very charming. I cannot recommend this one for any other purpose. It is a cool-house kind from Australia and New Zealand.

A. gracillimum.—This is a singularly beautiful Fern, as will be seen by the illustration. It is, I think, a garden variety of *A. cuneatum*. Indeed, when I obtained the first batch of seedlings of it I was laughed at for continuing to prick them off. Perhaps I should not have been so assiduous had I not seen a seedling on the wall which was putting on the narrow beautiful fronds. It comes true from seed, and as a pot specimen nothing can be more beautiful; the fronds also are exquisite, covering the flowers with which they are arranged like a delicate green veil. The fronds should, however, be cut at the last moment, or be cut and submerged for twenty-four hours before using on account of being so delicate. The plant originated in Mr. B. S. Williams' nursery, and likes stove heat. *A. glaucophyllum* is an elegant cool-house kind from Mexico. It also does

Adiantum gracillimum.

occasional light sprinkling with the syringe, are necessary. The following kinds will be found very interesting, as they will produce a pleasing appearance in the house and will afford a variety: *A. affine* is a pretty species, producing its fronds from a creeping rhizome. The fronds are each about a foot or 18 inches high when well grown. They are some two or three times divided and rich deep-green in colour. These fronds are valuable for mixing with flowers arranged in a good-sized vase; black ones are also invaluable for mixing with flowers for

the warmer house during the growing season. It is a small-growing plant with fronds several times divided, and the pinnules are somewhat leathery in texture, dark green on the upper side, glaucous beneath. *A. Ghiesbreghtii* is a bold, handsome plant, erroneously named *A. scutum* when it first appeared in our collections. This was at a time when Ferns had a good hold upon the public. The fronds grow some 2 feet in length, and the pinnules are numerous, large and of a pale green in colour. It is invaluable for cutting for table

3775.—Plague of ants.—As the ants are now swarming on the Peach-trees, I expect that they are attacked by scale insects. At this

decoration. A stove Fern from the West Indies. *A. tenerum*: The fronds of this plant as well as those of the last-named form fine objects for setting up with cut flowers in a vase, and for this purpose should be submerged in water for a night or more before they are used. The young pinnales are soft crimson and very elegant. Widely distributed in tropical America. *A. trapeziforme*: A fine, hold-growing plant, one with large pinnales, and producing fronds some 2 feet and 3 feet high. This is quite distinct from any other species named here, and it may be cut and used for mixing with Grasses and flowers in the winter months. There are several others somewhat like this which may be similarly used. *A. macrophyllum*: An erect-growing plant possessed of much beauty. The fronds, which vary from 10 inches to 20 inches high, are pinnate, the pinnae being red or crimson when young, changing with age to pale-green, and becoming of good thick substance. A warm-house plant from Jamaica and other West Indian Islands. *A. pedatum*: I cannot allow this enumeration to pass without including in it the most beautiful species of Maiden-hair Fern that is grown, although despised by many because it is hardy. The plant is deciduous, and, therefore, not so useful as many of the kinds. North America. *A. peruvianum*: A hold-growing plant, making firm and hard pinnae with jet black stipes. This plant has now been introduced long enough to admit of its being grown for cutting. It is a warm-house plant from Peru. *A. Williamsi*: This makes fronds some 2 feet or more long. The pinnae, smaller than those of *A. tenerum*, are bright green, the stem being slightly clothed with farinose powder at the base. It is a cool-house plant. J.

ORCHIDS.

ONCIDIUM CONCOLOR.

This is an elegant plant, possessing one of the peculiarities of many spring-blooming plants in its colour, which is of a bright rich-yellow throughout, and its flowers last a very long time without distressing the plant, if they are not allowed to become wetted by the syringe. Another reason why this plant should be grown by all Orchid lovers is the fact that it thrives well in a cool Orchid-house. This plant first flowered in English gardens some fifty-three years ago, having been sent over here from Rio Janeiro, and upon this account it was kept in a warm-house, and in those days we had not become aware that many Orchids would grow best with very cool treatment, and the consequence was that the plants did not thrive, and it was very scarce in our collections for many years; but now it is common and to be easily obtained, and I think for this we are indebted in the first place to the Messrs. Veitch and Sons, of Chelsea. *O. concolor* is a dwarf growing plant, having small ovate bulbs, which are slightly furrowed, and they bear a pair of leaves each, which are strap-shaped, of good substance, and rich-green; the spike proceeds from the base of the new growth; when about half formed, it is drooping from the weight of its many flowers—sometimes as many as fifteen and eighteen flowers—each measuring fully 2 inches in length, composing one raceme, but upon others flowers in much less numbers are borne. Indeed, I saw a short time ago a few racemes bearing only five flowers, and these were erect, so I do think I am correct in saying the racemes become pendent from their own weight. These flowers are of a rich, bright yellow, the lip being very large, and when freely produced they produce a charming effect. This plant grows best, and it shows best, when in bloom, suspended from the roof in a small basket. Earthenware or Teak-wood will suit it, but I prefer the former. They should be well drained, and the soil composed of peat-fibre and chopped Sphagnum Moss. It likes a plentiful supply of water from the syringe and to its roots when growing, and in the winter just sufficient should be given it to keep it moist, and, of course, the syringe can then be laid by. I like to keep this plant in the cool-house with the *Odontoglossum* during the summer months. The species being a native of the Organ Mountains, a more natural temperature can be accorded it, but if the growths are made up, it may be wintered in the

Cattleya-house. This does not mean warmer treatment, for both houses are allowed to fall much lower at this season, and this *Oncidium* will not withstand so great a fall as the *Odontoglossum* from the mountains of New Grenada and Mexico. MATT. BRAMBLE.

ODONTOGLOSSUM CITROSUM.

I AM in receipt of several enquiries from readers asking why they cannot flower this plant? And I also have received a spike of flower of a very nice variety from "E. Bishop," saying it is the first one that has opened out of seven upon his three plants. He says his plants have been grown entirely from my instructions, so that I fear my other enquirers either have not grown the plants strong enough to flower, or they have not rested them dry enough, or they have not been kept sufficiently cool. I think upon previous occasions I have remarked that this species grows naturally upon Oak-trees, at a great deal lower elevation than any other *Odontoglossum* found in Mexico, and that it likes more sun than any species of the same genus, and it was from the fact of not knowing this that our first want of success in flowering it arose, I have no doubt, for a plant bearing a single spike, and that tied up to a stick, was looked upon in my young days as a great achievement. I have, however, now frequently observed grand plants with five pendent spikes reaching to 2 feet and 3 feet in length, bearing many of their sweet scented flowers, and I have seen nearly a hundred spikes hanging all at one time, which presented a sight that was fairly captivating. Roez himself writes of it: "Great was my surprise to see the trees clothed with a profusion of this Orchid; the stoutest branches of the Oaks were loaded with them, their pendulous spikes being a yard long, and each one bearing as many as thirty expanded blossoms." And now "E. B." wants to know how to grow it? The plant should be placed in hanging-baskets, for in this manner it can be given just the treatment it requires by hanging it in the sunshine; and then, again, when the plants flower the pendulous spikes can take their natural habit, and I have observed when hanging over water they appear to grow longest. These baskets should be well drained, and the soil should be of good brown fibrous peat and chopped Sphagnum Moss. This should be pressed down firmly, but carefully avoid giving the plants too great a quantity. During the summer, its growing season, the plants should be hung up in the stove or the Cattleya-house, and during suitable occasions an abundance of fresh air is admitted, and shading should only be resorted to the middle of the day. They like a liberal supply of water during their growing season, but in resting the plants should be dried, and then be removed to a cool-house where the atmosphere is dry, and the plants should not have a drop more water than enough to keep the bulbs from shrivelling before the flower-spikes begin to show themselves in the new growth, when they may have a little, which will soon cause the spikes to grow; and when this has begun, the plants may be again taken into warmer quarters, and be given a greater amount of water. The flowers usually appear in the month of May. MATT. BRAMBLE.

ANORHECUM SANDERIANUM.

SOME flowers of this Orchid come for a name from "Charles Beaton," and he asks what I know of it and its cultivation? Now there appears to be some confusion about this plant more or less; but as "C. B." says his plants of this kind were gathered in the Comore Islands, I do not hesitate about saying they are the same plant which was named *Sanderianum* by Professor Reichenbach in 1858; but I think a plant from Madagascar I have seen with narrower leaves and shorter spikes of bloom, under the name of *A. medustum*, approaches this species very closely. However, this, you may take for granted, is the plant sent me for a name, but if the two Orchids are identical I cannot say. The *Angraecum* in question I once saw with a spike about 2 yards long; no flowers had then developed upon it, and I cannot say if any did, for I have never seen the plant since that time, which was two years ago, nor have heard anything of my friend since. Of course, this was a

very unusual length for a spike of the plant, but I have seen it with very long spikes laden with its pure-white, long-spurred flowers, which are very handsome, and last long in perfection. This plant thrives well upon a block of wood, but I prefer small, shallow, earthenware pots, well-drained, using fresh and growing Sphagnum Moss alone about its roots. It requires a good heat all the year round, say a temperature that does not fall below 63 degs. or 65 degs., and moisture must be maintained (though in a less degree in winter) all the year round. The usual time for this plant to flower is in April and May. I would recommend some few other species of *Angraecum* to my readers having heat enough, but unfortunately there is not much variety in the different kinds, for all or nearly all of them have flowers of a more or less pure white, but there is the famous *A. sesquipedale* with its peculiar metallic-green leaves, and its so-called foot and a half flowers, although I do not remember seeing a flower which was true to its name. Then there are the singular free-flowering and beautiful *A. Leonis*, which has equitant leaves, and the charming little "Fishbone" *Angraecum*, *A. pertusum*, the elegant little plant first seen alive in this country with Messrs. Veitch, and recently referred to in *GARDENING*, the fine West African *A. Chailleanum*, and many others, to say nothing of the great *A. eburneum*, the giant of its race; but the flowers of all these are white, and therefore are not to be tolerated generally in an amateur's small collection of Orchids. MATT. BRAMBLE.

MILTONIA CUNEATA.

This is a truly beautiful species, and some flowers of an excellent variety of it came to hand for a name from "James Wood," I was glad to see, for it is not often that so unusual a species comes from an amateur. I say unusual somewhat advisedly, for I remember the time when this was a very rare Orchid; but it has been more plentiful during the last few years. There does not appear to be much record of the introduction of this plant, but there are records of its being in cultivation nearly fifty years ago, and it was said to come from Brazil. This was strikingly brought home to me a few years ago, for upon visiting a gentleman recently returned from Rio, he said: "I have some Orchids in the garden, which I shall be glad if you will name for me," and upon my looking them over I saw great quantities of this plant. Upon questioning him as to where they grew, he said the plants were all gathered by himself on his Coffee plantation near Rio, so that my readers having this *Miltonia* may be sure that it will succeed best in the warmth of the Cattleya-house. This plant was named *Oncidium speciosum* by Reichenbach, and, indeed, the aspect of the plant is similar to that of an *Oncidium*, and its flowers, which are borne upon an erect spike, remind one somewhat in shape of those of *O. tigrinum*. The sepals and petals are oblong-lanceolate, nearly equal. In the flower before me they are nearly wholly of a dark chocolate-brown, tipped with pale yellow, and having at intervals an occasional streak of the same colour, reusing through the brown, lip large and flat, clawed at the base, pure white, having two raised fleshy plates on its base. It is very handsome, lasting a long time in perfection. The usual period of flowering is rather earlier than the present time, and I have seen it in bloom early in the month of February, but it is always welcome. I have found this species very easily grown, and flowering so early in the season gives one an opportunity of giving it reasonable shade so as to maintain a good colour without hindering its blooming; but I like to expose it to the sun in the autumn more freely in order to ripen its growth, and thus ensure its flowers at the end of the winter or the beginning of spring. It thrives well in a pot, drained thoroughly, and potted in a mixture of good brown fibrous peat and fresh Sphagnum Moss. Water freely when growing, and maintain a nice moist atmosphere, but when growth is past it should be very carefully watered, but do not let it suffer from drought. I have frequently heard it called a difficult plant to bring through the winter, and from the very fact of its being kept in too dry a state I imagine, having found that those who so completely usually subject their Orchids to a drier winter-treatment than I approve of.

MATT. BRAMBLE.

FRUIT.

APPLE COX'S ORANGE PIPPIN.

ON the great merits of this Apple there is little need to enlarge, for the simple reason that it is one of the most popular varieties in cultivation—in fact, it may be said to be the best praised dessert variety that exists. What also is most satisfactory, it fully deserves all that has ever been written in its favour, and if all we hear and read of it is true, the time is not far distant when this excellent Apple will be plentiful in the markets throughout the late autumn and winter months. Partial failures will happen with this as well as any other variety of Apple, but a complete failure I have never known—at any rate, where one or two trees are not solely depended upon. I have five good sized trees growing in different parts of the garden, thin crops being produced by the majority. All flowered well in spots, too, of bearing freely during the two preceding seasons, but the buds are not sufficiently self-protecting, and the fructifying parts of the flowers suffered from frost accordingly. That is the one weakness of Cox's Orange Pippin, but, luckily, it is not often that the trees are subjected to such severe tests as they were this season. According to my experience, particularly good pyramids are not easily grown, the habit of the tree being somewhat straggling, and I hold that the most profitable trees are those on the Crab stock, and grown either as large bushes or half-standards. Very good trees can quickly be had by simply cutting out the leader of a pyramid as received from a nursery, the side branches being shortly notched back at each winter pruning till enough shoots are obtained to make a well-furnished tree, after which thinning out and foreshortening are all the pruning necessary or advisable. In some cases it is needful to stake up some of the principal branches, or otherwise the heavy crops they produce will weigh them down to the ground. The illustration accompanying these notes was from a photograph of part of a branch of a freely grown tree framed out in the manner just described, and the fruit on such branches, being well exposed, colours beautifully. This plan of training suits my purpose better than any other, but it does not follow that it is the best under all conditions. On the contrary, the variety succeeds admirably on dwarfing stocks, and either grown as a bush, cordon, or horizontally trained, and on a variety of soils. Very good fruit is sometimes obtained from orchard trees, but much the best samples are gathered from those more highly cultivated, and which also are less liable to be disfigured by gales of wind. Not only is Cox's Orange Pippin of excellent quality, or second to none in this respect, its appearance also being greatly in its favour, but it possesses the great merit of remaining in season from November to March inclusive. It is the favourite exhibition variety, especially for showing in single classes, none but the very best samples of Ribston Pippin standing any chance against it. The variety was raised by Mr. Cox at Colnbrook Lawn, Slough, Bucks, somewhere about the year 1830, and is said to owe its parentage to Ribston Pippin, though it bears little or no resemblance to that good old Apple. W.

OUR READERS' ILLUSTRATIONS: Fruiting-branch of Apple "Cox's Orange Pippin" Engraved from a photograph sent by Mr. W. Cooper jun'or, Marlton, Froms, Somersetshire.

make no progress whatever in ten days' time the best plan would be to root the Vines out and plant afresh, remaking the border. The present is a good time to plant new canes already growing in pots; even these struck from eyes this year will make good canes before the end of summer if the house is kept warm, avoiding direct draughts of air blowing over the Vines. Syringe the foliage twice daily during bright weather, and supply the roots liberally with water. Train the Vines up with one single stem, plant wholly in the inside border, making up but a piece yearly, say 4 feet wide to begin with, adding about the same each year. If the soil is 2 feet 6 inches deep, that will be ample, underneath this place 6 inches of drainage, laid to a fall, so as to obtain a free outlet for surplus water.—S. P.

— It is most unwise to dress Vines with paraffin. They will probably shoot up from the bottom. The strongest shoot can be left, and, if all is well, they will fruit next year.—E. H.

3510.—**Apricot trees against a south wall.**—It is not wise to regularly syringe the trees for another month, especially as the weather is still cold at night. If the leaves are infested with insect pests, these should be got

— Against a south wall is the best position for Apricot-trees, and they may bear well this season if the frost did not touch the blossoms. It would be unwise to syringe them at this time of the year; but the truth is that at no time do Apricot-trees need syringing. The object of syringing Peach, Nectarine, Cherry, and Plum-trees is to keep the leaves free from insect pests and parasites, such as the various species of the aphid tribe, red-spider, &c.; but the Apricot is not likely to be attacked by them, and if syringing is resorted to at all it would be to wash the dust off the leaves during dry, hot weather in summer.—J. D. E.

— It will be better not to syringe Apricot-trees till the weather gets warmer. When the east wind has departed, and the nights are warmer, a wash with the syringe or engine will do good.—E. H.

3520.—**Black Hamburg Vine.**—Are you sure yet that there are no signs of bunches on the side-shoots? It is rather early to determine this in an unheated house, where the growth must necessarily be late. In some cases the bunches do not show until the formation of the fourth leaf on the side-shoots. There is no fixed rule for this, although the bunches do, as a rule, show at the second or third leaf. I should advise "H." to allow the side-growth to extend say five or six leaves on each side of the main rod, if space admits for a full development of so many shoots, then pinch out the point of each. Lateral growths will then push from the joints below; these ought to be pinched in at the first leaf, and the sub-laterals at one leaf also. Allow the leader to grow to the full length of the roof, then pinch out the point, and manipulate the lateral and sub-lateral growths in the same way as advised for the side-shoots. If fruit does not show on the Vine this year, syringe the foliage every day about 4 p.m. with tepid water during fine weather, which encourages freedom of growth, and assists to keep insect pests in check. Whether the roots in an outside border will require much water or not depends so much upon the weather and the state of the border. If the soil is heavy and the drainage not good but little will be required. If the soil is opposite in character and the drainage good, and the weather be long dry after the first week in May, an occasional soaking with tepid water will be of service, as also will the mulching with horse-mannure. If this has been laid on all the winter, it will be wise to throw it on one side for a week to allow the sun to warm the soil.—S. P.

— This appears to be a case of excessive vigour in the Vine, the result of which is that the rods were not properly ripened. You appear to have pruned the rods right enough, but I am afraid you treat the roots too kindly. If the border was well made the Vine would not require any further manuring until it is well cropped with Orapes. You had led the two rods extend up to the top of the house and then stop them. The laterals on each side may be allowed to grow about 18 inches on each side, and then be regularly pinched as young growth is made.—J. C. G.

3517.—**"Spot" on Gooseberry-trees.**—Your trees are affected with what gardeners call the "red-rust." It is a kind of a fungoid growth, consequent on the plants growing in a poor soil. Your only remedy is to get the trees into a more vigorous condition by well manuring the soil about the roots of the trees. If available, well soak the soil with manure-water at once, and then fork in some rotten manure, and lay a thick mulch of the same material on the surface as far away from the stems as you think the roots extend.—J. C. G.

rid of without delay by syringing the trees with some insecticide, such as Killbright, dissolving 2 oz. in 1 gallon of warm water, or soak 2 lb. Tobacco-paper in hot water, adding 2 lb. soap; this quantity will suffice for 30 gallons of water. Strain the Tobacco-water thoroughly before mixing with the hulk, or the syringe would be choked with the fine pieces in applying the mixture. The best time for syringing the trees at this season is in the morning about 8 o'clock, or a month later at 4 p.m. The next day give them a thorough washing with clean water, to cleanse the trees of both insects and any sediment that may have lodged on the leaves. Many of the failures to grow Apricots are traceable to an insufficient supply of water to the roots during the summer and after the fruit is gathered. Where the soil is light in character Apricot-trees absorb a quantity of moisture from the soil, and it should be replaced freely. Liquid-mannure ought to be given sparingly; it is apt to create a too vigorous growth, which is detrimental to the life of the tree, inducing cancer and premature decay, to which Apricots are so susceptible. If the trees make growth too freely the roots ought to be shortened at the end of September, inducing them to make more fibre, which sustain the trees, in a far greater proportion than long, bare, fibreless roots do.—S. P.

352.—**Vines dressed with paraffin.**—Seldom do Vines recover that have been dressed with paraffin in a raw state. It is a dangerous practice even when heavily diluted with water. There is no antidote that will resuscitate the Vines that are apparently dying from the effects of the dressing of paraffin. If the young shoots

HOUSE & WINDOW GARDENING.

THE LYRE-FLOWER (DICENTRA (DIELYTRA) SPECTABILIS) FOR A WINDOW.

This graceful plant, with drooping racemes of pink and silver blooms, is easily cultivated in a window, and requires no special heat. As the leaves gradually decay during the summer the roots become strong, especially if put into a border of good soil as soon as they have finished flowering; they can be potted up in November, or later, with as little disturbance as possible, and placed in the window of a room without a fire, with plenty of air, until they start into growth. Any attempt at forcing them at this early stage results in weak foliage and poor flowers; but when the plants are in full growth they may be given the sunny corner of a room window, in which there is a fire daily; plenty of air, except during sharp frost, will still be good for them. They must never be allowed to droop for want of water, but at the same time they should not be watered until the surface-soil of the pot is too dry to stain a finger laid on it; indiscriminate soaking of pot-plants in winter is a fruitful cause of weakness and death amongst them, water being needed more often when the plant begins to open its blooms. After these are finished, which will not be until June, the plant should be divided and placed at once in the open air; if possible, in a good rich sunny border, where the leaves will ripen off gradually during the summer. If a border cannot be obtained, the roots may be divided after flowering, and repotted at once in well-drained pots, with an ordinary potting-compost of leaf-mould, one part, to loam or turf-mould, two parts, adding a sprinkling of soot and sand, and if the loam be not rich a very little soil from an old hot-bed. The pots may be sunk in ashes up to their rims in a yard, or in a box of ashes over the "leads," the plants being watered in dry weather. They will then start into fresh growth, and they will be the better for a little liquid stimulant. Take indoors in the late autumn. L. R.

3258.—**Treatment of Palms, &c.**—I should think the plants require repotting. The great point with house plants is to keep the leaves well sponged, and the soil in moderately moist condition. If they have not been repotted for some time, and the soil has got thoroughly worn out, repot them, using good loam mixed with sufficient sharp silver-sand to make it moderately light. This is a good season to repot. *Aspidistras* require a similar compost, and peat will suit the *Pteris*. Repot with care, removing a little of the old ball, but not so as to damage the roots, and after potting give water cautiously, as if the soil is kept too wet the results will be unsatisfactory. A little more warmth for a time may be afforded. It will assist the plants to get established more quickly.—C. T.

3480.—**Worms on a lawn.**—A soot and lime dressing is very beneficial to the ground as well as very objectionable to worms; also I imagine you did not roll your lawns sufficiently after laying down the turves. Had you any loose soil under them? If you had I fail to see how they could die away altogether. Rake well the ground at once, sow a bushel (or two would be better) to the half acre, and mix up a compost of one quarter soot, one quarter lime (slaked), and half good soil. Roll well, and whenever you see the worms appearing roll again. It is the looseness of the soil that prevents the Grass-seed thriving, or the matured plant either, for that matter.—S. J.

It is almost impossible that worms—that is, earth-worms, should have destroyed the turf; in fact, they generally improve it. But perhaps the destroyers were not earth-worms. This you might know by the appearance of the earth thrown up. If ordinary worm-casts, then the occupants of the holes must be earth-worms; if not, dig down and see what has made the holes, and send me some specimens. It is getting late to lay down turf now, and you will have to take care and keep it well watered in dry weather.—G. S. S.

3514.—**Nasturtiums and annual Sweet Peas.**—It is not necessary to raise these now in the greenhouse. In fine cases out of ten they will do better in the open air. If sown under glass do not give them much heat, and move to a cold pit or frame as soon as they are up before they get green, and plant out when well hardened.—E. H.

THE KITCHEN GARDEN.

NOTES ON BEET.

The Crimson Ball and Globe varieties of the Egyptian or Turnip-rooted Beet are very superior to the old form, and ought certainly to quite supersede the latter. Not only do they quickly attain a serviceable size, but they also keep admirably, the quality at the present time being fully equal to that of the best of the long-rooted varieties. They will succeed well where the latter fail, a rather poor or shallow soil

Beetroot "Dell's Crimson."

suiting them admirably. On deeply cultivated rich ground they are apt to grow rather too strongly—become objectionably coarse, in fact; but this difficulty can easily be obviated by sowing later, or say, about the second or third week in May. They are heavy croppers too, for if the drills are disposed 15 inches apart the seedlings may be set 4 inches apart, and further thinned when the forwardest are near the size of tennis-balls, and therefore fit for use. I have hitherto grown the Turnip-rooted forms principally for early use, not considering them equal to *Dell's Crimson* and such like for winter use, but in the future the globe-shaped forms will be more extensively cultivated, as they please the cooks as well as those who eat them. For affording early supplies of tender highly-coloured young roots they are indispensable. A considerable gain will be effected by sowing a pinch of seed now in a pan or box of soil, placing it in heat to germinate, the seedlings being grown to a good size near to the glass in a pit or frame, and then transplanted, that is to say, dibbled out 9 inches apart on a warm border. Fairly early roots can also be had by sowing seed at once on either a warm-border or in a sunny, open spot. Frost occasionally destroys the very early sowings, but this risk may well be run, while birds have in many cases to be kept off with nets, or an occasional dusting of soot and lime may be given while the dew is on the plants, this also saving them from slugs. The end of April or early in May is early enough in most localities for sowing the main-crop of Beet. In this case also coarseness is most objectionable, and if the ground is strong and has been well manured for the previous crop, no manure ought to be given for the Beet. It is possible to err in the opposite direction, poor ground not growing Beet quickly or large enough, small and stringy roots being of no value whatever. If solid manure is used, this should be dug in rather deeply so as to prevent the top roots coming into contact with it too quickly, forking being the inevitable result of the latter occurrence. *Dell's Crimson* is in my opinion the best main-crop Beet in cultivation, and it is also known under many other synonyms. It is of neat growth, the foliage as well as the roots being very richly coloured, but it is scarcely vigorous enough for poor soils, and for these the Cheltenham Green-top and *Fragell's* Exhibition are more suitable. If either of the latter is grown on strong ground, defer sowing the seed till the middle of May, and draw the drills 15 inches apart, eventually thinning out the seedlings to about 8 inches apart. *Dell's* requires less space, and the drills for this variety may be 12 inches apart, planting the plants from 6 inches to 8 inches apart at the final thinning.

3496.—**Planting Asparagus.**—Asparagus may be safely transplanted now if the plants can be obtained near home. The best time for planting is when the young shoots are about a couple of inches above the ground; but I have transplanted when a foot high. I generally place a little fine rich compost over the roots, and water thoroughly as soon as planted; but if the plants have to travel far in weather like this, the chances of success are not so good.—E. H.

It is a good time to plant Asparagus from the 1st to the 20th of April, care being taken not to injure the young shoots, which will be pushing out from the crowns of the plants at that time. When planted at this season of the year they grow away at once, and if the ground is well trenched and heavily manured the plants grow with great vigour. They require well looking after, and a stick should be placed to each plant in order that the shoots may be tied to it and prevented from snapping at the base in a high wind. This last is of the utmost importance, for if the growing shoots are destroyed, or part of them, so much will the roots be weakened for next season. If dry, sunny weather continues, it will be necessary to mulch and water the plants.—J. D. E.

3497.—**Peas for show in July.**—I am not acquainted with the Californian Wonder Pea. If it is the same as American Wonder it is a dwarf early variety, and is not adapted for exhibition, as the pods are small. It would stand no chance in competition with the best Marrow Peas. To have Marrow Peas ready for exhibition the third week in July they should be planted at once. Early Peas, such as American Wonder, will be time enough in three weeks hence.—R. H.

3513.—**Treatment of Tomatoes.**—So long as the Tomato-leaves are healthy, let them remain on the plants. If the plants are crowded, and it seems desirable to let in more air and sunshine, the leaves may be shortened back, as half-leaf will be better than cutting away altogether.—E. H.

If the plants are making a strong growth, and especially if they stand at all closely together, it would be as well to shorten the lower leaves back as suggested, but not before the plants have commenced fruiting. A moderate amount of defoliation lets the air and light in between crowded plants greatly to their benefit, but if carried to excess it is injurious.—B. G. R.

3503.—**Jerusalem Artichokes.**—It is not doing the best for them to plant Jerusalem Artichokes in a north aspect. They will grow there, but the result will be better if planted in some open, sunny spot. They are propagated from the tubers like Potatoes, and pretty well every bit will grow, though it is best to use good sets. If smooth tubers are selected year after year for planting, the roughness which is generally a characteristic of the Jerusalem Artichoke may be refined away to a great extent.—E. H.

3518.—**Treatment of Seakale.**—Old Seakale plants when so large as those mentioned in this query are not so good for use as younger ones. The plants are always best the third year from the seed. We are using Seakale here all through the winter and early spring, and I sow a quart or two of seed annually to keep up a succession of young healthy plants. Crowns will form where the plants were cut over; and the old crowns taken off and planted deeper into the ground will also form roots freely, but the crowns of these old plants always run to seed, and are not so valuable for outting as young plants.—J. D. E.

You may cut the old Seakale stems off and use them to form new plantations. If as long as you state, cut into pieces 4 inches to 6 inches long, and plant in rows with a dibble. The old roots left in the ground will form new growths, which should be thinned if too many appear.—E. H.

3521.—**An old Asparagus-bed.**—Better make a new bed. Salt will not kill Couch Grass without injuring the Asparagus roots. Seeds may be sown now where the plants are intended to remain, thinning them out to from 12 inches to 15 inches apart in the rows. I like the single-row system at intervals of 3 feet.—E. H.

Potatoes as ground-cleaners.—Whilst the value of a good breadth of some strong-growing, disease-resisting Potato cannot be too highly estimated in its food-producing sense, it has considerable value also in its cleansing and disintegrating influence on rough, foul soil. Passing Sandown park, Esher, last season, I could not but note with much satisfaction the spectacle of a large number of working-men hard at work trenching up several acres of old and very tough pasture land, which had been placed

at their disposal as allotments by the racecourse company. That trenching was in this case the only method of bringing the ground into a useful condition for cropping was evident, as the Grass was long and the roots deep. The only fault to find with the work was that it did not seem to be deep enough, as the crops of whatever kind following would have to be sown or planted almost into the turf. The two evils to be encountered, and which might make the allotments for a couple of years, perhaps, something of a white elephant to the tenants, were a plentiful stock of wireworms and a good deal of coarse Twitch or Couch Grass growth. From the wireworms no crop would be safe, but one of coarse, strong-growing Potatoes would perhaps suffer least. Still farther, no crop would be as efficacious in helping to check, by smothering the surface with foliage, the grass Grasses, that would otherwise grow rapidly; whilst the strong roots of the Potatoes would prey upon the decaying sods, and during the summer thoroughly disintegrate them. Thus henceforth this old pasture would be in good clean working condition, and were it allowed to lie fallow all the following winter, being occasionally turned up to allow rooks and starlings to get at the wireworms, it might be materially freed also from these pests.—D.

BORECOLES AND THEIR VALUE.

As far as private growers are concerned, the green curled Borecole or Scotch Kale (see cut) is the most generally popular, and deservedly so. Perfectly hardy they are not, but it is not often the crop is lost, and the tops are usually available during the worst part of the winter, the side-shoots following in due course. Read's Hearting is both the best in point of quality and the least hardy, while all the rest are very succulent and tender when properly cooked. This season every green leaf has been gathered in cottagers' gardens, so scarce has been, and still is, the green food within the reach of the poorer classes. Cottagers' Kale crops heavily and is fairly hardy, but the quality is not so good as that of the ornamental Kale. Asparagus or Buda Kale is among the hardiest of the winter greens, and not unfrequently proves of great value. It is naturally dwarf, hardy, and late, being only just growing or producing shoots at the present time. Being kept closely gathered, whether required for use or not, early flowering is prevented and abundance of very succulent and agreeably flavoured greens are had throughout May and sometimes well into June. Private growers, too, often overlook the good qualities of this kind of Kale. In a conversation I recently had with a market grower of good experience, he asserted that, taking one season with another, no variety of winter greens paid so well as the common Thousand-headed Kale. This is largely grown by farmers for sheep feed, and after a mild winter is not wanted for any other purpose. When, however, other greens are very scarce, the Thousand-headed sells readily in the market, the average price this season being about 5s. a "lug," a west country term for a square rod. It is out very hard, so that consumers who pay 2d. and sometimes as much as 3d. per pound for it have a rather large proportion of stalks and old leaves to cook or not as they please. It is not a suitable variety for garden culture, but for the open fields and allotments it is one of the best that can be grown. Borecoles generally ought to be finally got out rather

be 30 inches apart, 2 feet dividing the plants in the row. The variegated Scotch Kales are very pretty, and though not much in demand for garnishing, are quite a feature in the kitchen garden, and can be used similarly to the ordinary forms. Their cultivation may also be similar, though if planted on somewhat poor ground the colours and variegation are more pronounced than is the case if highly cultivated. Both the Asparagus and Thousand-headed Kales may be sown where the plants are to grow, and this is the simplest way of growing them. They ought to have the benefit of a rather rich root-run and a good open position, the seed being sown from now up to the end of May thinly in drills not more than 2 feet apart. If raised somewhat earlier the plants should be freely thinned out, or left, say, 18 inches apart; but if late sowing is resorted to, then they may well be left 12 inches apart. All that is further necessary is to make good any blanks by transplanting, and a serviceable lot of greens should result. I.

OUTDOOR PLANTS.

PLANTING PÆONIES.

As the season is rapidly advancing, no time should now be lost in planting these noble herbaceous plants. Indeed, an earlier date than the present may be preferable for various reasons, but it is not always possible to accomplish everything at the right time, and it is remarkable how much these plants resent removal at any time, as the following will show: A year or two since I had occasion to replant a somewhat crowded hatch of the old Double Crimson. The plants were of good size, and had in the previous year produced fine flowers, three to six on a plant. Everything being ready, the plants were lifted and replanted in about an hour, occupying a position adjoining another and similar hatch of the same variety. The work being so quickly done, I naturally thought that the plants would suffer but little, particularly as the soil was not shaken from them more than was possible. In the result, however, those replanted made but puny growth, bloomed

seasons such plants may be flooded once or twice a week, applying liquid manure alternately with clear water. They love moisture as well as deep and rich soil, and too frequently receive insufficient supplies of the former in hot summers when their flowering is complete, bloom inferior in quality being produced in the ensuing year. Always plant them in open ground away from tree roots or shrubberies that would quickly take the moisture from the soil. Pæonies occupy a high position among hardy perennials, and no pains should be spared to grow them to perfection. J.

3516.—Plant for a centre of a bed.—

You have a wide selection of hardy and tender plants if you care to use them. I think, however, that your choice inclines to the latter. In any case you would have had a more definite reply had you given the size of the bed. Amongst hardy plants I should say that Yucca gloriosa would do admirably. The nearest approach to anything like a Cactus for a central plant are one of the greenhouse forms of Sempervivum. S. arborescens is quite a stately plant, so is also S. phaloides, only of a bolder character. There are also several forms of the Dracenas that will do in the open air in summer.—J. C. C.

— A Cactus will hardly be suitable. A group of succulents is very well to show off by contrast their curious and quaint forms, but for such a position I should try a Dracena lœvis, or one of the hardier Felms, such as Senecio elegans. If a cheaper thing is wanted plant one of the dark-leaved Castor-oils (Gibson) or a variegated Malva.—E. H.

— If the bed is large you might have a small plant of the American Aloe in the centre, which has a fine effect, or its variegated variety, Pachyphium bracteatum, Sempervivum arborescens atropurpureum, a bold growing plant, with striking dark-coloured leafage, or if the bed is not too formal or large a plant of the well-known Agapanthus umbellatus would be suitable. It has fine leafage and heads of blue flowers.—C. T.

3504.—New Zealand Flax.—This plant will doubtless stand the winter in many districts of Ireland. I once saw in County Wicklow all kinds of New Zealand trees and shrubs which had stood through the winters of many years, for they had grown into very large specimens. It had better be planted out now and have all the season to become established. It is better

Head of "Scotch Kale."

fully a week later, and produced much smaller flowers than the companion batch that was left alone. The planting was done very early in the year. I mention this so that intending planters should be prepared to wait for Pæonies to establish themselves, and when this is done the reward will come annually in their large handsome flowers. Few plants are of more simple requirements, and, given a deep and rich soil, they soon make headway. It is almost impossible to over-mannure them. Liquid manure may be given to established plants in unlimited quantity with excellent results, and in dry

to let the side-growths form roots before they are taken off; large growths with a few roots attached form plants in a very short time. I have tried planting them in pots, where they soon become established, but near London the New Zealand Flax is not hardy out-of-doors.—J. D. E.

— This plant may be divided the same as the Pampas Grass in May, or off-sets with roots attached may easily be obtained from early plants. It is not generally hardy, but will succeed in warm, sheltered places in Ireland and round the south and west coasts of England. It will grow in any good soil. Keep the plants well supplied with water so

The Double Crimson Primrose.

This is a sickle beauty which everybody who knows it aspires to grow. I think there can be little doubt as to its partiality for light, rich, moist land, and some gardens may have the right conditions to suit it. It loves plenty of leaf-mould, incorporating it deeply with the soil, to be divided and set more deeply every spring-time just after flowering, if a similar operation has not been done in the previous late summer, a time which some people prefer in order not to interrupt the flowering process. I have always found, however, that if a fair piece of root-stock could be taken with each division in the month of March or April the plants would not only grow vigorously in the newly-prepared soil, but the flowers would open perfectly, though perhaps a little later than usual. Set the divisions well down and never allow the plants to go longer than two years without transplanting.—J.

THE GLADWIN (IRIS FÆTIDISSIMA).

This is a native of England from Durham southwards, and is abundant in Hampshire, Suffolk, and other of the southern counties. Hooker says it is naturalised in Scotland, and that it is rare in Ireland. As a native it probably really is, but as a half-wild or naturalised species it is abundant, especially near Dublin, where, however, it does not fruit so freely and so beautifully as in Southern England. It seems to favour the limestone formations in Ireland as in England, where it is also plentiful on the chalk of Kent and Surrey. In aspect this plant is more sombre in leafage than any other species, its foliage being densely clustered, of a dark-green colour and not glaucous, as is the case with most other rhizomatous kinds. Its flowers produced in May, several on a scape, are of a dingy purple or lilac colour with darker veins, these being succeeded by large trigonal fruits not unlike those of *Iris pseud-Acorus* in shape, but when the pods or capsules burst, as they do in the early winter season, the brown valves are lined inside with clusters of coral-red or orange berries or seeds. The handsome fruits are shown in the accompanying engraving of about a third the size of nature, and when grouped simply with a handful of the deep-hued evergreen leaves they form a distinct and handsome ornament. Of late years large quantities of these fruits have been sent to Covent-garden and other flower markets, where they are sold readily as indoor ornaments. They are sometimes used as a substitute for Holly-berries, which they somewhat resemble in colour and size. The plant is worth a place in the wild garden, or it may be naturalised on hedge banks and near water, or on the Grassy outlying portions of the lawn, where its foliage acts as a foil to brighter things, such as Snowdrops and Daffodils. There is a variegated kind sometimes met with in gardens, but it is not so handsome as the wild type. B.

3526.—Laying out a flower bed.—As you wish still to have hedging plants, try *Tuberous Begonias* of good colours, edged with *Dactylis glomerata variegata*, with a final margin of Tufted Pansies. This will be rather a flat arrangement, but you may also make a fine feature by planting good *Fuchsias*, mixed with Tufted Pansies, as a groundwork to the bed; outside this central arrangement *Ageratums*. *Fuchsias* will make a good change, and prove not only effective but informal; but the *Lobelia fulgens*, such varieties as *Queen Victoria* and *Firefly* are very rich in colour, and if used freely in the centre, the groundwork may be Tufted Pansies or *Ageratums*, a fine contrast with the Pansies outside this centre, and the margin of *Centaurea rugosus*. I should make use of the following plants not mentioned by you, except one: Scarlet *Lobelia*, *Tuberous Begonia*, *Fuchsias*, Tufted Pansies, and such things as *Ageratums* and *Dactylis*. Some of the richest and brightest, yet most informal, beds I have seen have been produced by these subjects.—C. T.

DIVIDING HERBACEOUS PLANTS.

This is the best time of year to perform this operation, as growth is now getting active, and the pieces strike fresh root very quickly, and cuts in the stem heal over quickly, such plants as *Hepaticas* may now be pulled in pieces, and replanted, a few crowns in each tuft, which will quickly develop into fine clumps. *Gentiana acaulis*, the loveliest of blue flowers, *Auriculas*, and *Polyanthuses*, *Daisies* for edgings, *Niellas*, etc., if carefully divided and replanted, flourish much better, and bloom for a greater length of time than if left undisturbed, while many of the larger growing plants, such as *Phloxes*, *Pyrethrums*, *Tritomas*, etc., need the soil renewing at least every alternate year, for being strong rooters and gross feeders, they soon exhaust the soil in their immediate vicinity, and if taken up, divided, and replanted on fresh, deeply-cultivated soil, they will repay the trouble by continuing to branch out and flower for weeks after those that have not had the same attention have done blossoming. It is advisable to do half the stock one year, and half the next to get the longest season of flowering possible, as dividing retards the blooming a little, although it prolongs the season much later; but by having a few established clumps for early flowering, and the rest divided for a prolonged season of bloom, there will be a greatly increased display, for a time of drought soon brings the flowering period to an end, unless there is plenty of food within reach of the roots of the plants, and it is then that the effects of good cultivation are most apparent. J. G., Hants.

3511.—Plants for a trellis work.

The autumn would be the best season for planting. I should recommend Red Honeyuckle, Yellow Jasmine, *Gloire de Dijon* Rose, *Pyrus japonica*, Clematis Jackmani, and the large perennial White *Convolvulus*. I would, however, plant a hedge of variegated *Privet* on the east side of the trellis as a partial shelter to the

The Gladwin (*Iris fœtidissima*).

flowering creepers; this will also greatly help the screen, since few flowering creepers are sufficiently dense in their foliage to offer much protection against wind.—A. G. BUTLER.

—These open trellises are not well adapted for climbers. They are so draughty. Tender things will not grow upon them, and the fact that they are required to break the east winds seems suggestive. The common hardy Honeyuckle, mixed with *Jasminum nudiflorum* and *Clematis Flammula*, will be pretty and interesting, and will be in blossom, more or less, all the summer.—E. H.

3463.—Time for planting bulbs.—On the 27th September last year I planted all my outdoor *Hyacinths* and *Tulips*—to the number of 250 of each sort. They are now in full bloom, and have been for some time, and very handsome they look yet. You may wait until 15th October if you wish, but it is safer and better to have all spring outdoor flowering bulbs in by 1st October. The same applies to *Narcissus* and *Daffodils*.—S. J.

3505.—Improving a lawn.—If the ground is merely "a collection of weeds," the best thing to do will be to dig it over, and bury the weeds well into the ground. It is easy during the process of digging to make the surface quite level. The best and quickest way to secure a nice green lawn is to obtain good turf from somewhere else and turf it over. This is

of necessity also the more expensive way; a nice green turf can also be obtained by sowing lawn Grass seeds, which can be obtained in mixture from any of the leading seedsmen. Watering the weedy ground with guano-water would cause the weeds to grow as well as the Grass.—J. D. E.

3508.—Seedling Pansies.—If you want to grow seedling Pansies fit for exhibition you must sow the seed about the middle of July, and early in October plant them in a cold frame to shield them from rain and snow. Frost will not hurt them if the ground is not saturated with moisture. To get flowers fit for naming, I should say you would want to grow at least 500 to secure half-a-dozen equal to the best exhibition varieties now advertised, and to do this you must obtain seed from the most reliable sources, and be prepared to pay a good price for a small quantity. As I write I have a lot of plants now in flower from the seed obtained from three of the best known strains, which cost me a good bit of money. The flowers are very pretty, and the variety of colours satisfactory, but not one is worthy of being named, chiefly for the reason that the plants bearing the best flowers are deficient in vigour, for even a well-formed and well-marked flower is of no use if the plant is a poor grower. If you wish to avoid a covert smile passing over the features of your fellow-florists when you are showing them your flowers you had better not attempt to give names to any of your stock until an independent party has decided on their merits.—J. C. O.

—These are very easily obtained from seed, and the young seedlings soon grow away freely in rich, deep soil. If the seed was sown under glass early in the year, and the plants were grown on freely afterwards, exhibition blooms might be obtained, but the best time to sow Pansy seed is in July. Sow in fine soil out-of-doors. When the plants have grown a little, prick them out, and plant where they are to flower from the middle to the end of the month of September. The plants may go out about a foot square, and in good deep soil they will begin to flower in March or April, and continue to do so until the end of the season. Bright colours, good substance of petals, and circular form of flower are the leading qualities.—J. D. E.

—You ask an interesting question. If you mean show Pansies you will have to get something unusually distinct and good for any one to merit a distinct name; but you may also select any fine bold coloured kinds likely to make a good garden flower, not thinking entirely of the exhibition. Pansies, especially the "tufted" kinds, have been much brought forward of late for the garden, and there are many pretty kinds, and something may occur amongst your seedlings to merit attention. But avoid giving a name, unless a flower is really first-class, and then give just a simple name only. The show Pansies are the florists' varieties of the old type, and may be either one distinct colour (self), or the ground yellow or white, the colours not running into the other, but with the belting and blotches clearly marked. As regards foliage, the upper petals may be coloured with varied shades; the lacing and blotches, however, on the other portion being quite distinct. The form of the flowers should be round, the petals closely arranged, and form a smooth, even bloom, of fine substance, velvety, the eye in the centre of the flower as far as possible yellow, and not "rayed"—that is, no rays or strips of colour radiating from it, whilst in respect to size, as in the case of most exhibition flowers, the bigger blooms, other points being equal, come first. If you find any promising variety in the "tufted" class, pay regard to its habit, freedom, and softness for the garden, apart from the colouring of the flowers.—C. T.

3494.—Water Lily seed.—I do not know where these can be obtained. Probably it is not to be bought. In the most likely catalogue of all—that of *Vilmorin Andreux et Cie*, of Paris—seed is offered of only one kind, and that the common white, and of three tropical species beside, but none of the fine kinds enumerated in my article.—A. H.

3500.—Hardy Water Lilies.—Write to M. Latour Marillac, Temple-sur-Loire, Gironde, France, for his list. I consider the present prices very moderate, as some of the best kinds are only about one third what they were three years ago, when the plants were purchased that were described in my last article.—A. H. O. 1893

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

3541.—Fence for a rockwork.—Would someone kindly give me a list of Ferns suitable to grow amongst rockwork in the open air with a waterfall in it?—ALPHA.

3542.—Angle for a coolinery.—For a coolinery to vinery facing due south, what is the most suitable angle? Forty degrees has been mentioned to me.—JOLANER.

3543.—Treatment of Fuchsias.—What treatment is best for Fuchsias which were grown from cuttings last year, and were somewhat neglected in the early part of this season?—F. H. H.

3544.—Narcissus flowers dying off.—Would someone kindly tell me the reasons of my Narcissus flowers dying off? Barely one open. They are growing in a border under a north wall.—G. H.

3545.—Dahlias.—I wish to ask the names of the best six Dahlias (to include only two Cactus) to plant in one bed, the blooms to match, or contrast? Do six more to mix up twelve altogether for show—four each Cactus, Show, and Fancy.—J. B. B.

3546.—Getting rid of worms.—Will someone kindly tell me how to get rid of very large worms in a lawn without injuring the Grass? I have tried lime-water, and it seems to fetch the little ones up, but it takes no effect on large ones.—J. H.

3547.—Ten-week Stocks and China Asters in pots.—What is the best treatment to attain a fine show of Ten-week Stocks and China Asters in 6-inch pots in an unheated greenhouse, and how many plants should be in each pot?—HARBOUR.

3548.—Potatoes.—I have recently had sent me some seed Potatoes. The name set with them is "Fucher's Frame." I do not know the sort. They seem to be a white round kind. Are they early, late, or medium, and to the name right?—J. B. B.

3549.—Pipy Celery.—Will someone tell me the reason why my Celery has gone pipy this last two or three seasons? I manure fairly, and water when required. I plant it deeply when I first put it in the trench. Is that right or wrong?—WORKMAN.

3550.—Selection of Dahlias.—Will someone please name the best six Pompon Dahlias, and the best six Show and Fancy kinds? Also the best Cactus, and if the Green Dahlia "viridiflora" could be shown as a Pompon in a collection?—DAVID FANCLER.

3551.—Aucuba japonica.—Is there any difference between Aucuba japonica and Variegated Laurel, or is there any such thing as Variegated Laurel? I think the Aucuba is sometimes called Variegated Laurel. Also, how can the Aucuba be made to berry?—D.

3552.—Flowers for a grave.—Will someone kindly tell me what flowers would be most suitable for a grave that only gets the sun in the morning? If possible, I should like flowers that will bloom most of the summer. The soil is not very good, being rather clayey.—A. W. H.

3553.—Perennials for beds.—Will any person kindly let me know the names of twelve good showy perennials to flower in summer? Different colors for twelve beds in flower garden. Also state their height! I like something under 2 1/2 feet high, and good bloomers.—D.

3554.—Dying Peach branches.—Is it better to wait until one side of a Peach-tree is quite dead, or to cut it off as soon as it shows signs of decay? What is the reason of and cure for "scald" on Peaches? Should blighted leaves be nipped off as in disbudding?—GARLAND.

3555.—Palm leaves dying.—Will anyone kindly tell me the reason of the tips of the leaves of a Kentia Palm going dead? They are sponged every week, and the plant is kept only moderately wet. It stands in a brass pot in the window of a drawing-room facing east.—L. M. L.

3556.—Emigration for gardeners.—Will someone kindly inform me the best part of America for gardeners to obtain employment? Are there any good openings in Canada for gardeners with slight knowledge of cattle and poultry, with and without small capital?—NOTICE.

3557.—Sewage-water.—The entire drainage of my house goes into a cesspool, with a very large overflow receptacle, whence it can be pumped out. My gardener, though admitting that it may do good if put on the land, considers that it would be impossible to use it for growing plants. My contention—supported by my recollections of Chinese horticulture—in that, properly diluted, it should be excellent for Raspberries, growing Peas, and, indeed, almost anything. I should be glad to know, if right?—H. G.

3558.—Seakale from seed.—Will anyone kindly inform me how to grow Seakale from the seed, both for kitchen garden cultivation and forcing in boxes for winter use, and are the roots that have been grown in deep boxes outside during the winter of any further use?—FARMERMAN.

3559.—Climber for a conservatory, &c.—Will someone kindly tell me the best climbing plants for a conservatory? I have a Tacsonia, Plumbago, and Passiflora princeps. The house has the full sun, and is very warm. Do Roses in pots do best in the shade or in the conservatory?—N. O.

3560.—Ornamentals from cuttings.—Is it too early to take cuttings of Malmaison, Miss Joliffe, &c., from plants which are in bud, or is it better to wait until the plants have flowered, lest they should get checked by removing the side shoots? The Miss Joliffe are bushy young plants.—OSMR.

3561.—Marchal Niel Rose in a conservatory.—I have a Marchal Niel Rose growing in a conservatory. It has just finished blossoming, and owing to the quantity of flowers which I have had from it, it looks rather weak. It is also attacked by green-fly. What treatment is best?—F. H. H.

3562.—Anthurium Scherzerianum.—Will anyone kindly tell me the reason why the blossoms of Anthurium Scherzerianum break off before coming into blossom? At first I thought that it was the gardener's fault, but finally one was seen breaking off by itself—i.e., untouched by anyone.—RINEA.

3563.—Manure for Potatoes, &c.—I shall feel obliged if someone will kindly inform me whether kainit and superphosphate are suitable manures for such crops as Potatoes, Onions, Parsnips, &c. If so, how should they be applied, and when? Any other information on the subject will be thankfully received.—MILL VIEW, Leicestershire.

3564.—Magnolias not flowering (grafted).—I believe there are two fine Magnolias here—one with south aspect, and the other in a corner with south and east aspect—on a wall. They have not flowered for two years, and how many years before that I do not know. What can be done to induce or help them to flower?—C. B. A.

3565.—Treatment of a Honeysuckle.—I had a slowly-growing plant of Honeysuckle (Lonicera flexuosa) a year ago on a verandah, and it got out down by the winter frost, which caused it to throw up numerous small root shoots in the gravel paths very untidily, but it did not flower any more. What would be the treatment for it now?—H. J.

3566.—Plants for greenhouse heated with an oil-lamp.—Wanted information as to names of plants, climber, &c., to furnish a greenhouse heated in winter only by an oil-lamp? The house faces south-west, and is built against the dwelling-house over the basement, 8 feet long, 6 feet wide, 12 feet high from basement floor to top.—ONOCERUS.

3567.—Rats and Water Lilies.—I have a pond a good deal frequented by water-rats. It is only about a foot or 18 inches deep. Would the rats be injurious to Water Lilies if planted in it? Water flows freely into and out of it, but still there is a good deal of coniferous growth which gathers in it. Is there any way to prevent it getting on to the plants?—D. H.

3568.—Tomatoes in a small house.—I have some Tomatoes to flower in a small house, 55 degs. night temperature. I have noticed that the blossoms, after some of the fruits have set, have, in some cases, dropped off the plants about a quarter of an inch from the stalks. Will someone kindly tell me the reason? I give plenty of air on warm days, and keep the plants plentifully supplied with water.—BRUCE.

3569.—Orange-tree from a pip.—I have a little Orange-tree raised from a pip. It is about two years old and 16 inches high. I intend having it grafted presently, but the wood is as yet quite soft, except just at the base. Will someone kindly tell me whether it would be well to cut it down in order to make it grow more bushy, as the stem, being so soft at the top, is apt to bend to one side?—A. H. H.

3570.—Vine culture.—I have just taken to a greenhouse, 22 feet by 16 feet, heated by a stove. There are two Vines—Black Hamburgh and White King; and roots to a border outside; stems as thick as my wrist. The past fortnight they have nicely broken into leaf. I shall be glad to know how to treat these successfully—ventilation, watering, feeding, &c.? I am now using a fire.—F. C. SALMON.

3571.—Salvia cocinea nana, &c.—Will anyone please let me know whether this Salvia is a perennial or half-hardy annual? Is some catalogue in it called a perennial, and in others a half-hardy annual. I am afraid to plant it out in a bed in the flower-garden, fearing that if it is perennial it won't bloom this year. Also, is Ageratum imperiale, dwarf blue, a good plant to make up a nice blue bed, or will it be showy enough?—D.

3572.—Jasminum nudiflorum.—Succeeding to a much-neglected garden, I find a yellow winter Jasmine, which has been permitted to grow for years unpruned, until it has formed a dense mass 8 feet or 4 feet thick. I wish my wall to look tidy, but fear if I cut it right back I shall lose all bloom next winter. What should I do? Also, what is the proper season and way of pruning this plant under ordinary circumstances?—H. G.

3573.—Bulbs from South Africa.—I have just received the following bulbs from South Africa. Should I plant them now or keep in a cool place till autumn, and is a temperature of 50 degs. sufficient for them? They are Watsonia triflora O'Brien, W. speciosa, Antholyza, Friesman's bulbocodium, Friesia refracta alba, Cytantheus angustifolius, C. obliquus, C. spiralis, Satsyrum coriifolium, Lachenalia aerea, Crinum aquaticum, and C. riparium.—T. B.

3574.—Forcing Seakale.—I have a quantity of two-year-old Seakale plants, which have been raised in a border of the kitchen garden, where the soil is a strong loam upon a stiff clay. How must I direct the gardener to prepare a bed upon which to force these plants next winter? What should they be removed, and what is the covering that should be used? The situation is cold and damp, in north-west of Yorkshire.—MRS. T., Woodlands.

3575.—Seed from Algiers.—I have had sent me from Algiers some seeds of the Geranium (query, Caroulier) tree, and should be glad of some information about it? Will it grow out-of-doors in this country, or if not, what amount of heat will it require? Would it be suitable for planting in a large bed in a conservatory? The seeds were sown in a pot in a warm greenhouse, and the young plants are about 2 inches high, but I do not know what to do next.—GRASSER.

3576.—Vines in a cool-house.—I should be obliged if some friends would give me particulars how and when to begin to disbud Vines in a cool-house? They have just begun to show bloom. Also, about tying them in, and when to do them second and third time? I had them done three times last year, but found I could not depend on the men I had, so I pruned them myself, and letted to do all that is required to them, if some friend will furnish me with all information?—H. W.

3577.—Keeping birds off Peas and Cherries.—Will someone kindly tell me the best way to keep birds off Peas, also a Cherry-tree? I have a very large Cherry-tree (standard). It bears a heavy crop of fruit every year, but I always have to gather them before they are ripe, or the birds would have them all. The sparrows are the greatest pests I have to contend with. With respect to the Peas, I can manage fairly well to keep them off with strings of black thread in their young stage, but when they begin to pod, then they attack them, and to me, it seems impossible to keep them away, and I lose quite half my crop. Locality, London, E.—PETER.

3578.—The right to rain-water.—I am living in one of a row of five cottages, and the rain-water from the whole of the roofs runs into my rain-water cask. The neighbours imagine they have a right to the water, and, if it is inconvenient to myself, come at a time to dip and take it away, oftentimes clearing the lot. Will someone kindly say if I have a right to move the outlet pipe to a place more suitable to myself? If so, I shall build it and put up a door to keep the other people off my premises. The pipes have been there for more than twenty years, but the property changed hands about ten years ago. I put the oak in its present position about three years ago. Before that time the neighbours used to catch the water in their own buckets.—WITNESSE ASKAS.

3579.—On cucumber plants dying.—Would "J. O. C.," or any experienced grower at Cucumbers, say what is the cause of plants dying away in the following manner? First symptoms are, curling of the leaves, next the aerial droops as if it wanted water in a day or so after another, and then the plant droops altogether. I have grown for several years, and had more or less plants go off like this, and cannot trace its cause. They are grown in a lean-to house upon a stage above hot-water pipes. The plants are about 8 feet high now, and I have just had one go off as in previous years. I have also had some go off while a dozen nice Cucumbers have been hanging. They are growing upon a mound of soil, as is always advised.—CUCUMBER KNOWER.

3580.—Chrysanthemum for out flowers.—Would "K. H.," or someone else, kindly give me with advice on the following? I have some nice plants of Chrysanthemum of M. Desgrange, Mrs. Hawkins, and a few others of that section, that I wish to grow for out blooms only. I stopped the most of them about three weeks ago, when 6 inches high. They are now making brisks. What I want to know is, am I to retain all the shoots from this break? If not, how many shall I retain, and also at what stage of growth shall I remove the shoots, if I have to remove them? It is advisable to pinch back the coming shoots? If so, what length shall I allow them to grow before doing so? I have also a few elegies. Will the same treatment apply to them? Any hints on their culture for out bloom will greatly oblige?—W. B.

3581.—Marchal Niel Rose in a greenhouse.—I have a Marchal Niel Rose in a greenhouse. From root to end of the bough it is 15 feet long. At the latter end of January it became full of buds, and looked very promising, and about ten days afterwards the foliage went off as if struck by lightning, and I could crumble it to powder. It has two stems, and about 2 feet from the ground it is split and cracked. They were the same last summer. It is an error to be removed! Is it advisable to pinch back the coming shoots? If so, what length shall I allow them to grow before doing so? I have also a few elegies. Will the same treatment apply to them? Any hints on their culture for out bloom will greatly oblige?—W. B.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3582.—Selecting bunches of Grape (Vitis).—When a Vine shoot sends forth two bunches of about equal size and value one must be removed, and, in a general sense, the one to be retained should be nearest to the parent stem.

3583.—Double Zinnias (G. L. M.).—Prick the seedlings off into 4-inch pots, and when thoroughly established they may be gradually hardened off. Planting out should be done early in June in the warmest spot available, and the bed of soil should be deep, rich, and rather light.

3584.—Destroying "American Blight" (B. R.).—Scrape out all you can of the "blight" from the cankered portions and crevices of the Apple-tree branches, and then apply pearlin-olil or Glucol Compound with a soft brush to the affected parts. It may be done even now, but the best time for the operation is during winter.

3585.—Stopping Vines (G. E. Powell).—The Vine should be stopped at two leaves beyond the bunch, and if each lateral shoot has more than one bunch on it, remove the smallest as soon as developed sufficiently. Be sure not to overcrop, and read GARDENING regularly, and you will get all the information you require from time to time. The best book on the Vine is "Vines and Vine Culture," by A. F. Barron, price free for 5s. 3d. from the publisher.

3534.—*Cosygyne corrugata* not flowering (G. Hill).—I do not know what can be the reason you keep this plant in the Catleya-house, for I consider the coolest end of the Odontoglossum-house more in accordance with its requirements, and in such a position I should place it. I consider it entirely your own fault the plant being without flower.—M. B.

3537.—*Cymbidium Lowianum* (B. J. W.).—Your plant which is just opening its flowers will certainly remain good until the end of May, if you keep the syringe from playing upon it. Do not move the plant from the house in which it has been grown, and in which it has opened its flowers, because they will keep the fresher, and the plant will maintain its vigour better.—M. B.

3538.—*Hypocylindrum robustum* (J. Ekin).—This is the name of the shrub you send. It has long, slender linear leaves, the rose-coloured flowers being seated on the axils of the leaves. I should not have expected to see it so early, but I am glad to see it at any time. It is a native of Australia, and should be potted in a mixture of loam and peat made sandy.—J. J.

3539.—*Lobelia in pots* (E. L. A.).—Sow the seed in a frame, and when the seedlings are up prick them off three in a 3-inch pot in light loam soil. Keep the plants close up to the glass, and give plenty of air. When the small pots are full of roots repot the plants into 5-inch ones, in which they should be allowed to flower. The shoots will not need stopping unless the growth is very straggling.

3590.—*Eschscholtzia californica* (C. W.).—You may now seed this plant in a warm house. Beware! It is said to be a very untidy plant; but I do not think it so, as its brilliant flowers should not be wanting in any garden. If you have not sown it in your garden before, you may do so now, and you will scarcely require to repeat the operation, as it will come up in abundance in winter years from self-sown seeds.—J. J.

3591.—*Cutting down an Oleander* (O. C. R.).—Cut down the plants at once to 12 inches or 18 inches. When the young shoots appear, and the weather is sufficiently mild, place it in a very sunny spot and give plenty of water, bringing it indoors again at about the end of October. This treatment should ripen the wood, and induce it to flower all the year round. The best cut for the Oleander is the fibrous loam, with a little silver sand added, and it should be pressed firmly around the roots.

3592.—*Green fly on greenhouse plants* (A. Phil.).—The best way of destroying greenfly is by light and frequent fumigations with Tobacco. When this cannot be done the plants, when not in flower, should be syringed frequently and thoroughly with Tobacco-water. This is best done in the evening, and then the next morning the plants should receive a thorough washing with clean rain-water, applied rather liberally with a syringe. To prevent the Tobacco-water reaching the roots the plants should be laid on their sides when syringed.

3593.—*Raising Marvel of Peru from seed* (B. G.).—Seeds of this plant should be sown as early in the year as possible in a warm house. As soon as the seedlings can be handled they should be pricked out in pots or peat about 2 inches apart, using a fine, free, and well-aerated compost. Keep them well up to the light, and about the end of May they may be removed to a cold frame, gradually hardening them to the full exposure. About the end of the first week in June plant them out in the open ground, choosing a sheltered and sunny spot in the garden for them.

3594.—*Treatment of a Palm in a window* (B. E.).—As the plant in question is in good health, and is root-bound, it would be an excellent time now to repot it into a also larger in a warm house. As soon as the seedlings can be handled they should be pricked out in pots or peat about 2 inches apart, using a fine, free, and well-aerated compost. Keep them well up to the light, and about the end of May they may be removed to a cold frame, gradually hardening them to the full exposure. About the end of the first week in June plant them out in the open ground, choosing a sheltered and sunny spot in the garden for them.

3595.—*Hardy Double Primroses* (A. R.).—These Primroses do best in cool, shaded quarters in the summer, such as the north side of a hedge or other outcrop. They should have plenty of water at the roots in hot, dry weather, and when the plants are in flower, weak acid or other manure-water would, no doubt, be beneficial, especially if the soil be poor. The best time to increase them by division is as soon as they have ceased flowering, and before hot, dry weather sets in. If you have no naturally-shaded place to plant them, then a few evergreen branches stuck amongst them will greatly help them to bear the often scorching summer sun.

3596.—*Propagating Hydrangeas* (A. R.).—These are very easily propagated from cuttings, which should be taken off in August, when the wood is partly matured. The cuttings should be about 3 inches or 4 inches in length, and the joints of the shoots should be severed, cutting clean just below the third or fourth joint. They can then be inserted either singly in small pots or several round the side of a 6-inch one. A good compost for them is a sandy loam, and the pots should be well drained. A slight bed should be prepared, on which place an ordinary frame, covered with a glazed light. Plug the cuttings in this, and keep them well moistened and shaded, and then they will soon strike root.

3597.—*Abutilon vexillarium* (J. Childs).—This is the name of the plant sent. It has small leaves for an Abutilon, and ten bright-red calyx and spreading corolla (of the flowers) of a light-yellow render it very conspicuous and pleasing. Abutilons are very easily grown plants, requiring a mixture of loam leaf-mould and peat made sandy. They require to be well-drained, and to be liberally treated as to water. A Vexillarium may either be grown as small plants, or it is very effective grown to specimen size; but I think it most effective when trained upon a wall in the greenhouse, where it will continue to produce a display until quite the end of June.—J. J.

3598.—*Treatment of an old India-rubber-plant* (N.).—The plant of this, which has become bare of leaves, should be headed back somewhat and be placed in a comfortably warm greenhouse. As soon as possible after the young growths make their appearance it should

be repotted, taking away as much of the exhausted soil as possible. Use a pot of about the same size as the one it is now growing in. It should be well drained, and the compost should consist of shaly peat and loam and some sharp silver sand. Return it to the warm greenhouse after potting, syringing the plant overhead daily, and shade from hot sun, and do not give much water at the roots until active growth sets in, when plenty will be required.

3599.—*Sparmannia africana* (R. B.).—This is the name of the flower you send. It is an old Cape plant, which has been introduced into this country more than a hundred years, and is still popular for cutting. Its sooty white flowers being very attractive all the year round. There is also a double-flowered form which is very useful. It flowers from about 18 inches in height, and grows some 10 feet or 12 feet high; but if you have no room for such large specimens, strike the young now, and make more young plants; then, when your plants get to large, you may discard them without feeling the loss. Pot them in loam, leaf-mould, and sand in a warm greenhouse; the plant will commence to flower in autumn and continue all winter.—J. J.

Names of Plants and Fruits.

Names of plants.—Y. R.—*Amaryllis formosissima*—J. Allen.—1, *Cattleya Trianae*, ordinary form; 2, *Odontoglossum vitifolium*; 3, *Ocoidium leucocollum*; 4, *Lycocata arnautica*.—M. Lessely.—1, *Odontoglossum luteo-purpureum*, poor form; 2, *Cattleya Sobreders*; 3, *Odontoglossum cirrhosum*.—James Wood.—2, *Miltonia oenacis*; 4, *Ocoidium Suttoni*; 5, *Ocoidium leucocollum*. Cannot name the *Hippestratum*.—E. Wright.—Cannot name the *Ferax*; too young. Seed again when fronds are fertile. —H. Jarrold.—1, *Deodorium Wardianum giganteum*; 2, *D. thyralliflorum*; 3, *D. nobile Cooksoni*.—Miss Bartlett.—The specimens gathered from a wall apparently *Draha muralis*. To other one is some *Crucifera* near to it; but the specimen is too poor the name. When sending again number them.—P. B. Chehana.—The Partridge-breasted Aioe (*A. variegata*).—B. A. Haag.—1, *Sisyrinchium grandiflorum*.—J. Hayes.—1, *Cypripedium Bedeni*; 2, *Achelia Barkeri*; 3, *Cypripedium Roebelii*; 4, *Ocoidium flexuosum*.—E. J. Jacobsen.—1, *Dendrobium superbum*; 2, *Dendrobium lermouanum giganteum*; 3, *Odontoglossum luteo-purpureum*.—Mrs. Banks.—*Dorolium austrarium*.—A. Suberberg, *Durina*.—*Acacia Verticillata*.—*Alnus*.—*Oreothylacium arabicum*.—D. S. B.—*Selaginella Krasskeana*, frequently known as *Lycopodium dendrolium*.—Mona.—Cannot name from a single leaf only. Send again when in flower. —D. J. P. Phil.—1, *Narcissus Herfordii*; 2, *Forsythia villoidissima*; 3, *Phlox subulata*; 4, *Dorolium austrarium*.—England.—Seed better specimens, and pack them safely. These sent were crushed out of recognition through being put into a slimy match-box. —Harry Windsor.—The specimens sent are apparently all the same, *Arum maculatum*; but they were much crushed up in transit. —C. Boulker.—*Lithosiphon floridula*.—R. M. B.—*Andromeda scribunda*.—*Chardonia*.—*Freesia rosea* var.—A. K. Hart.—*Cymbidium Lowianum*.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

H. O. W.—Apply to Messrs. James Veitch and Sons, Royal Exotic Nursery, King's-road, Chelsea, London, S.W. Instead of Mr. E. W. B. you have given a very good flower of the *Malmalium Carnaticum*. If you have treated the plant in any special way we shall be glad to receive a note from you on the matter. —Beginner.—Please repeat your queries, and write each one on a separate piece of paper, and on one side of it only. There is no book that we know of that will give you half so much information as *GARDENING ILLUSTRATED*. If you take and read it regularly and attentively. —Constant Reader and Subscriber.—The question as to Water Lilies is replied to in this issue of *GARDENING ILLUSTRATED*, page 104. —North.—"Brown's Forestry" is the best book for you. —James Fleming.—Apply to Messrs. Harbison and Sons, The Grange Nurseries, Bedala, Yorkshire. —Pete.—Take in and read *GARDENING ILLUSTRATED* regularly, and you will get all the information you require. —Spruce Beer.—Write to the editor of *Pharm and Home*, published at this office. —Edward Buckell.—Please send Orchid again. We have not received it. —A. M. Kitchen.—Apply to Mr. E. Hobbay, Cavendish-park Nursery, Rock-road, Cambridge. —W. A. B.—Dust over the rows with soot and lime, and place some lines of thread over the Peas and Beans. —Helen H. Harris.—The Apple-tree roots have evidently got down into a cold, wet subsoil. Lift them and replant in good loam in November next, and well drain the soil if water-logged at all. —Young Gardener, Devon.—The Tomsto-plants are conkered at the root. Have they been much crowded in the seed pans?

Catalogue received.—Farm Seeds, &c. Messrs. Toogood and Sons, Southampton.

Books received.—"Manures: How to Make and Use Them," by Frank W. Semper; "Onions for Profit," by T. Grolner; "Calery for Profit," by F. Grolner. Published by Messrs. W. Atlee Burpos and Co., Philadelphia, U.S.A.

POULTRY & RABBITS.

3422.—*Chickens and an incubator*.—"Zeno" does not make it clear what particulars he stands in need of. The eggs are placed in the machine as soon as possible after they are laid, freshness being a most important part of the business. It is a mistake to use stale eggs, even under a hen, but to do so with an incubator is a court failure. Incubators are of various sizes, according to their size and the reputation

of their manufacturer. A fifty-egg machine would cost somewhere about five guineas. Most, if not all, are heated by a lamp fed with paraffin. The incubator is best fixed in a room where fresh air can gain access; but it must not stand in the glare of the sun, nor should it be within reach of hemmoring, or any other disturbance, or the frequent jars will seriously interfere with hatching. There is no reason why the machine should not be fixed in the room to which "Leno" refers, as the warmer the place the less heat will be required from the lamp, but the temperature should be as equable as possible. "Leno" will not be likely to do much good by keeping chickens in a heated room. They are far better when they gain access to the fresh air. Of course, incubator-hatched chickens must be provided with artificial heat, but this is best provided from a regular brooder or foster-mother.—DOULTING.

BIRDS.

3500.—*Feeding Canaries*.—I should be pleased if any one of your readers would tell me what kind of food is best for sea Canaries, and for young ones?—A. R. Rader. 3501.—*Robins building*.—Will anyone kindly tell me what time of year Robins build their nests, and if they build in shrubs, and also what they feed on?—L. Lovva of Birds.

REALLY GOOD THINGS.

CARNATIONS.—Mrs. Muir, success holder, 6d.; Germanica, yellow, 3d.; Keyard's Holly, apricot, 6d.; Mrs. Laird, superb blue, 6d.; Hero, white, 5d.; Bala, salmon, rose, 4d.; Gloire de Nancy, immense white, 4d.; Redburn, white and clear, 4d.; Salisbury, white, 4d.; Salbury, rose, 4d.; Pink Her Majesty, magenta, 7d.; Old Crimson Globe, true, 2s. 6d.

FLOWERING CHEYSANTHS.—Lovely hardy summer and autumn bloomers, grand for cutting. Deiranga, white; Hawking, yellow; Roi des Precoeds, or soon and gold; Pierce's Sealing, bronze; F. Polo, red; Precoeds, golden; and other lovely varieties. Twelve to name, including above, 2s. 3d.; 2s. 4s. 3d.; 4s. 7s.; females an upright 6d. each.

SPECIAL SEEDS for present sowing.—Exquisite Sweet Peas, named kinds, mixed, 6d. and 1s. per packet. Poppies, white, scarlet, yellow, separate or mixed, 6d. and 1s. per packet. Carnations, double pinnated, strain, 6d. and 1s. per packet. Magnificent fancy, unusual, 6d. and 1s. per packet. Sweet docters, 6d. and 1s. per packet. Canterbury Bells, 3d. and 6d. Wallflower, blood-red and golds, 3d. and 6d. per packet. Foxgloves, 3d. per packet. Sweet William, mixed, 3d. and 6d. All free. Cash.

RICHES, Florist, Boady-lane, Chester.

18. PER DOZ., FREE.—*Polyanthus*, Pinka, 1 Guiney; 1s. 3d., *Auricularia*, from best 6d. pair, White *Violas* (10 packets).—B. ARMITAGE, Horticulturist, York.

WHITE FLOWERS IN WHITE FLOWERS II.—Hartland's "Seed-drift," Double White Fimbriated Poppies. Will also numerous quantities of bloom sown now. The flowers are beautiful fancy, unusual, 6d. and 1s. per packet. Seed 6d. or packet from—HARTLAND, Seadam, Cork, Ireland. Established 1810.

HARDY FERNS.—10 rare roots, 16d.; 100, 2s. 3d. free. 11 best, 1s. 6d. per pair. *Polystichum*, *Cheilanthes*, *Adiantum*, &c.—H. ANDREWS, Shute Ashted, Devon.

CHEYSANTHEMUMS.—1 doz. best Exhibition varieties, including Mrs. Spaulding, Mrs. B. Coleman, La Triomphe, and others of equal merit, carefully packed, free for 1s. 6d. Old Crimson Globe, 6 for 1s. 6d., or 2s. 9d. do.—GRANGE Shepperton green, Middlesex.

GOOD KING HENRY (MERCURY).—The grandest vegetable in cultivation, superior to Asparagus, 40 plants, 2s. 6d. free.—T. HALL, 2, Koscoe-street, Bathurst.

AMERICAN BELLINI, grand *Auricularia*, & *Hepatica*, 2s.; "Daisy Miller" *Auricularia* (double, ruby), Yellow *Primroses*, 1s. doz. free.—LANE, Sydney, N.S.W.

GERANIUMS, autumn rooted cuttings.—Boarlet *Vaccaria*, 1s. 3d. doz.; 7s. 100. Flower of Spring, 6d. doz. Free. *Perilla*, 2s. doz., post free for cash. JAMES BARTON, Northbridge-street, Robertson, Brisbane.

FERNS.—Trade.—Stove and greenhouse, 25 Ferns, 2s. in pots, 1s. 100 Large, in 3-in. pots, 6s. doz.; seedlings, 6s. 100. *Cyperus*, *Oreocallis*, *Rhachista*, and *Aralia*, 6s. doz. *Poa*, *Palma*, *Margurita*, *Hydrangea*, and *Polygonum*, 1s. each. A. omissum large, 6s. and 8s. doz. in pots. *Ficus tremula* and *A. omissum*, for making large plants quickly, 1s. and 3s. 100, packed and put on rail free for cash. J. SMITH, London Fern Nursery, Loughborough- Junction, London, E.W.

VIOLETS.—Plant now for fine blooming next season. *Wolleraia*, giant single blue, 2s. 6d. doz. *Coate* *Brazza*, double white, 1s. 11. *Campbell*, double blue, very sweet, 2s. 6d. doz. *Harley*, 1s. doz. in beautiful kinds. Lists free. *Eden* *Poppies*, *Coronilla*, *Mrs. Sinkin* pink, and many other good things, in pot.—MRS. WATSON, Hestwall, Cheshire.

SPECIAL CHEAP OFFER.—6 *Geraniums*, 6 *Dbls.* 17 *Geraniums*, 3 *Holothrys*, 3 *Fuchsias*, 3 *French* *Lavender*, 2s. free. Also 2t Yellow *Calceolarias*, 1s. 6d. free.—A. TOMKIN, Florist, Sidcup, Kent.

SURPLUS PLANTS.—10 *Begonias*, 1 *Sparmannia*, 1 *Bryonia*, 3 *Dbls.* *Petunias*, 3 *Pleas*, 3 *Leopolds*, 2 *Ferax*, 3 *Phobias*, 3 *Chrysanthemums*, 5 *Geraniums*, 1 *Coronilla*, 2 *Genistas*, 1 *Vallisneria*, 2 *Solanums*, 2 *Bourvardias*, 54 plants, 6d. free. New *Chrysanthemums*, E. Siebeck, Mrs. Banket, and 1 beautiful *Palm*, worth 2s. gratis with order.—Head Gardener, 64, Warwick-st., Bathurst.

MERCURY (King Henry).—To cut in May and onward plant, now. Is delicious, superior to Asparagus, no extra cultivation, grows roots, 10, 3s. free.—ANDERSON, Mill Hill Gardens, Lo. a. n. t. n. Wilsden.

DAHLIAS a Specialty.—*Dahlia*s, strong *Perilla* *Shaw*, *Pompano*, and *Oactus*, finest varieties, named, 3s. 6d. per doz. post free. *Catalpa*s on application. JOHN THORNTON, 15, Elm-st., Driffield, Yorkshire.

GARDEN WORK.

Conservatory.

Young plants of Tree Carnations will require shifting on, and when established will do better in frames than houses. To do these well they must have good loam, and if the loam of any particular neighbourhood is not suitable it will be better to get some from a district where Carnations do well. The same remark applies to Chrysanthemums, though these plants require heavier loam than Carnations. There is a very great deal in getting the right kind of soil; loam from the beds of good plant cultivators, and it is worth some effort to get the right kind and quality. The soft, silty loams are the best, as gritty matter can be added when required. Next to good loam, which is used more especially for soft-wooded plants, good peat is an absolute necessity for hard-wooded stuff, and it is not often that much peat can be placed upon local supplies. It is far better to purchase the small quantities required for small collections of plants than use the material obtainable from some of the local sources. This is the best season for repotting hard-wooded plants. In shifting or healthy young specimens do not break the ball nor yet lacerate the outside roots by digging among them with a potted trowel, as is sometimes recommended. All that is required is to turn the plant out carefully, remove the crooks from the bottom, and fix the ball of the plant firmly upon the foundation of drainage and rough peat which has been carefully prepared for it, arranging the ball so that there will be one clear inch in space at the top when the potting is completed to receive the water. Be specially careful not to sink the coils of hard-wooded plants too deep in the soil. Earthing up the stems will be fatal; ram the soil in firmly and repot when the roots are in a healthy state as regards moisture, neither too wet nor too dry, and then the day after potting give a good soaking with a roset pot, and afterwards trust to the old expedient familiar to every plant grower of tapping the pot. Plants which have been raised from seeds or cuttings should be potted off and shifted on and kept in warm, close houses or pits to get started. Free graying, pinching if necessary, is essential for the next two months of their harden off and stand outside on coal-ash beds, keeping them well supplied with water. Old plants, after being shortened back a little, may as soon as they break be shifted into 32 sized pots, and be grown outside to get the berries well set. Sometimes these plants are turned out at pots into a warm border, and they usually do very well so treated; but the berries are then later in ripening, and some time is lost in getting the plants established. Shade is necessary now for flowering plants.

Stove.

There is still time to put in cuttings of anything of which young stock may be required, as the soft young shoots will quickly strike in a brisk bottom-heat if kept close. One of the evils to be guarded against now is over-crowding; but such things as *Boerhaavia*, *Amarrillid*, and *Begonias* may be moved to an intermediate house or warm vinery if the plants are quite free from mealy-bugs. *Palme*, *Falala*, *Anthurium*, and *Crotone* are now getting larger from year to year, and sooner or later some of them have to be disposed of or sacrificed in some other way. It is generally possible to exchange large plants for small ones of newer introduction and it is quite possible to keep a collection of plants which are well cared for up to date in the matter of new things in this way by exchanges, if the matter is sanctioned by the employer, but not otherwise. The training of some others (*Allamanda*, *Clerodendron*, *Bougainvillea*, and *Baphoea*) should have frequent attention, and if the plants are grown in pots, the fast-growing shoots must not be allowed to twine about indiscriminately, or there will be a difficulty in taking them down to get them arranged on the wire trainers when the blossom-buds appear. Seedling *Saxifraga* and *Gloxinia* will do better in a close pit, where they can be shaded on as they require more space. Many *Orethia* which have completed their blooming will require repotting or basketing; very rough fibrous peat, with fresh Sphagnum chopped small, forms the best compost, the peat to be well filled with drainage. Using such porous materials it is necessary to press them down firmly.

Ferns under Glass.

These are getting into good condition now, as most of the old fronds of Maiden-hair will have been weeded out. Where Ferns are required for cutting the shade must be of a very light character. I prefer screen blinds to roll up and down, as in this way there is a considerable part of the day when the plants will be growing under bright, clear glass, and this would not be the case if summer cloud or whitening is employed; and where appearance has to be studied blinds are best. Seedlings of the species of which we are now in winter will now be ready for pricking off into pans or boxes, to be afterwards transferred to small pots. It is a great mistake to crowd young growing specimens; it quite spoils them for the time being.

Propagating-house.

The stock of bedding plants will now be pretty well provided for, and as soon as room can be spared there are seedling *Begonias* and other young stuff to be helped out. This is a good time for grafting *Oranges* or any other hard-wooded plants. The process is very simple. The scion or graft, which should be a young, healthy shoot, is placed on the side of the stock, a slip of bark and wood having been removed so as to leave a small tongue of bark at the bottom, into which the base of the scion is fitted. The bark of stock and scion should join on at least one side. Tie with moderate firmness, and reduce the head of the stock a little, but still leave on plenty of foliage to keep the sap in circulation. The plants after grafting must be kept close and shaded till the union is complete. An expert hand has but few failures.

Cold Pits and Frames.

As the bedding plants can be moved on to temporary shelters, some of the pits may be got ready for *Melons*, *Cucumbers*, *Green Ginger*, or *Capekums*. Bottom-heat

is necessary for *Cucumbers* and *Melons*, and this can generally be supplied now with stable-manure, sometimes mixed with any of the waste materials to be found in the garden, such as Grass obtained from the lawns. The best prepared beds should be reserved for the *Melons*, so to obtain good-flavoured, well-grown *Melons* the bottom-heat must be continuous. I have had occasionally good *Melons* when the bottom-heat declined before the fruits were ripe in a bright, sunny season.

Window Gardening.

Many are now beginning to make arrangements for the outside window display. Boxes are being repainted and new boxes made. If more effort was made to cover the boxes with foliage and flowers by planting creepers and other free-growing plants along the front, the material with which the boxes are made or its colour will not much signify. I think a perfectly painted box should be completely hidden within a very short time of its being filled.

Outdoor Garden.

The ground now is very dry, and at present there are no signs of rain. Light soils should be firmed by treading. This will be beneficial to *Carnations*, *Panicles*, *Roses*, and most things which have had the spade or fork used among them during the late winter or early spring. Masses of *Wallflowers* are now very bright and showy, and they always flower best in firm ground. The middle of May is quite time enough to sow *Wallflowers* for next year's blooming. *Canterbury Bells* and other *Campanulas* should be sown at once to get the plants strong for blooming next season. Flower seeds will not grow till rain comes unless they are watered, and in all cases watering should be combined with shading. *Rhubarb* leaves spread flat on the ground are better than most things for assisting the germination of seeds. Newly-planted *Evergreens* are having to die, and many things will suffer, and not a few lost altogether, unless some pains are bestowed upon them. The first thing is to mulch with old manure or Green-ore something; the second is to give water enough to keep all the roots in a moist condition; the third in the case of valuable specimens is, if possible, to rig up some temporary shade and use a syringe or garden engine freely once or twice a day near the foliage. With proper attention there will be no losses. In purchasing new hardy plants for the borders or rockery, it has an advantage in it in as much as the present is the time to make the selection, transplanting a certainty. *Anemone*, *Viola*, *Gemata*, *Fasciola*, and other kinds of creepers may be planted now out-of-doors to cover walls.

Fruit Garden.

Continue disbanding *Peaches* on walls, and have the Tobacco-powder distributor handy to case insects are present. This saves such a lot of time and trouble. At present the fruit prospects have not suffered materially; some of the blossoms will fall, so matter of course, to the manifest benefit of the crop and the trees too. Very few people have the courage to thin fruit sufficiently, so that a cold night or two, which does the work for them, may be looked upon as a blessing in disguise. The sunhille has done wonders for fruit on trees under glass. *Peaches*, *Grapes*, *Pige*, and *Melons* never looked better, but though this glorious sunshine has gladdened the gardener's heart, it has increased the work immensely. *Melons* have reached up, requiring almost daily attention in tying and stopping; *Vines* had demanded constant attention in thinning, stopping, and tying down. In the early houses sub-tentative had grown at a wonderful rate, necessitating constant rubbing out or pinching. Below the branches the best course is to put out, and above the branch pinch in to one leaf. There are various opinions about feeding *Vines*. Where the borders are shallow and the drainage ample, stimulants, either sprinkled on the surface and watered in or dissolved in the water and applied in this way, must be used very freely. Like in begin the use of stimulants as soon as the berries are thickened, and give a further dressing when the stoning is completed. Whatever stimulant is used is sprinkled on the border and watered in.

Vegetable Garden.

Early *Potatoes* that were planted in February will now push through the soil, and must be sheltered in some way, or the frost will cut them off. Drawing a ridge of dry soil over them will save them for a time, but this is a kind of negative protection; some sort of covering would be better. I have saved a crop by putting *Evergreen* branches among the plants and tying them there. No branch should be long enough to touch the ground, and the plants are better than they are now. What a nuisance sparrows are among young *Peas* as soon as they move through the ground. Wire guards are essential so long as the *Peas* do not grow through before that time arrives. Ten guards must be taken off and the sticks placed in the *Peas*. There is more than one way of using *Pea* sticks. The best way is to stick them in the ground in a slanting position. When one side of the row has been staked, place the sticks on the other side in a perpendicular position. Fewer sticks will suffice by the way of using them over the upright plant. Continue to prick out *Cucumbers* and see that a sufficient stock of *Winter Greens* is grown. Even the earliest districts might sow now. Olive liquid-manure to *Cauliflowers* and *Lettuces*. Apparage beds in cutting will be benefited by a free and copious application of house sewage; if very strong dilute it with plain water. It has been a good time to wage successful war upon the weeds; the hot dry, sunny weather is a splendid tool. I am in favour of the Dutch hoe because it leaves a free and open surface. The hoe that trends on his work sometimes plucks the weeds again. E. HOOPER.

Work in the Town Garden.

Even in unheated houses *Tomatoes* may now be safely planted out; but, of course, only strong and carefully hardened plants ought to be employed, while, if they have to stand in any way near the glass, some mat, soaking, or a blind of some kind must be drawn over the stock on frosty or very cold nights. During the summer season, or, say, from the middle of April until the end of October, *Tomatoes* succeed very well in town gardens, and with proper treatment bear abundantly; but during the rest of the year they are not worth house room unless the atmosphere is moderately pure and light and sunshine plentiful. The planting-out system is also decidedly preferable to the culture, though the plants usually succeed better.

ably well in boxes of moderate size. Pelargoniums of the Zonal section are now breaking into a beautiful bloom, and even in smoky localities produce a very gay effect, though neither the trusses nor pipe are ever quite so large as in the pure country air. Five-inch and 6-inch pots are the best also in which to flower the plants, unless large specimens are wanted, when they may be potted on into 8-inch or 10-inch pots; but in all cases large pots are undesirable. Always pot firmly, using good rich loam, and keep the plants on a cool bottom near the glass, with plenty of air in fine weather and light shade from hot sun in summer. Plants to flower from April till July or August should be potted the end of February, and another batch potted the end of May will come in to succeed them until the November fog set in, after which the blooms will refuse to expand where the air is more than very slightly smoky laden. The ivy-leaved varieties also are extremely floriferous and useful, especially for window-boxes, balconies, hanging-baskets, &c. These need even less pot-room than the last, and do not suffer from want of water, but when in full bloom and pot-bound both classes should be rather liberally supplied with weak liquid-manures. *Asters*, *Stooks*, and other half hardy annuals may now be successfully sown on a sheltered border of tight rich soil outside, and in this way often do better in the end than those sown under glass, as they are less liable to become drawn or to damp in banks, &c., though they are, of course, liable to coming into bloom before these started the sowing of the month. The *Salpiglossis* are very pretty subjects to this class with beautifully veined blossoms, and suitable either for pot culture or the open borders; these are better sown early. *Bouvardias* are now breaking into fresh growth, and must be freely syringed over head, but keep the soil on the dry side and repot when a little advanced. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from April 29th to May 6th.

Planted several rows of *Soulet Runners*. Dwarf French Beans were sown on a warm border a fortnight ago; they will be sheltered when the cold of the week is over from spring lettuce. Planted out *Cauliflowers* raised under glass; the earliest *Cauliflowers* are coming on under hand-lights, and a long row has been planted in a trench along the front of a thorough-house close to the wall. I have cut *Cauliflowers* from to a trench even before those were ready under the lights. I mention this to show that where there are no lights early *Cauliflowers* may be had by planting in a very warm position in a well-manured trench, with a ridge of soil to form a protection along the front. Sowed the main crop of *Peas* in a warm and large, warm room. *Chicory*, also for forcing, has just been sown. I have sometimes sown *Chicory* fortnight later, and the roots were quite large enough; if sown too early the plants "bolt" when placed in heat. Planted out early-sown *Leeks* in trenches; also two rows of early *Celery*. Sowed several kinds of *Marrow Peas*, including *Veitch's Perfection* and *Ne Plus Ultra*. I want a good many *Peas* at the end of July and through August and September. Used the hoe everywhere among growing crops to keep down weeds and midges, the closer the hoe is pushed through the soil, the better. Put in cuttings of various kinds of Herbs, including *Sage*, *Thyme*, *Tarragon*, &c. Sowed *Cheerill* and made a new bed of Mint. By thrusting a knife down a few inches into the soil the young shoots can be cut off with roots attached, and these planted out 6 inches apart will soon fill up and be useful for gathering. Mulched all outtings with an inch or so of old leaf-mould between the rows. Put in a lot of *Mrs. Sinkins* Pink cuttings on a hot-bed; the plants are intended for forcing. Through a press of other matters I am laborious about the plants, and will soon form rows. Sowed *Spinach* between rows of *Peas*. It potted *Azaleas* and other hard-wooded plants which have flowered; the plants will be kept rather warmer and closer for the present to encourage root action and consequent growth. Dug over and prepared a piece of land for sowing hardy plants, such as *Wallflowers*, *Sweet Williams*, *Hollyhocks*, &c. Watered recently-planted trees and shrubs; this is being done about twice a week, and will be continued until rain falls copiously. The trees have been weeded, and the weeds which are being sown to store in the walled south wall. Commenced disbanding *Peaches*, meeting the advances of the green-fly by the use of Tobacco-powder; this is superior at this early season, when the nights are often cold, to all forms of washing. Divided the stock of *Double White Primulas*; they were heavily mulched some weeks ago with *Cocoa-fibre* and ash, and roots had begun to form, so that I expect every piece will make a good plant by the end of the summer. Pricked out *Stocks* and *Asters* in beds in the open air; position for these will be wanted for filling up in a difficult out of *Campanula pyramidalis* (*Chimney Campanula*) to form a background to a long border. Top-dressed *Cucumbers* in a house; also tied down and stopped; the growth has been marvellous during the late sunny weather. Thinned *Grapes* in the second house, and took out a few more berries from *Hamburgh* in an early house which have now about finished stoning. Of course, not much thinning is left to be done. Crowded in a few bunches appearing to be crowded. It was better to cut out a few of the earliest berries, so that those left might have room to grow to the full size. Top-dressed *Vine-borders* with artificial manures, chiefly *Patent Nitrate*. I used this last season, and found it very beneficial to the *Grapes*; it may be used freely without doing harm. I have used 2 lb. to the square yard, and shall probably repeat the dressing later on in the case of the late varieties. Shifted on late-staked *Chrysanthemums* into 5-inch pots; the earliest plants have just been placed in 7-inch pots, and will shortly be placed in the open air altogether; at present they are shaded under a framework of wood, covered at night with canvas.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated with equal good results.

TREES AND SHRUBS.

LARGE FLOWERED OR HYBRID CLEMATIS.

The accompanying engraving shows the effective beauty and interest that a good variety of Clematis may possess when well grown and not too much restricted or trained. A wreath of silver stars like this enforces our admiration, even although the background be only an old black fence of tarred beards, a few wires being strained across it to keep the plant from falling down. Seeing how beld and lovely these larger hybrid Clematises are when vigorously grown, the wonder is that we so seldom see them used in places almost overdone with the forms of C. Jackmani. Such noble varieties as Lady Caroline Neville, lanuginosa, lanuginosa nivoa, Lady Bovill, Symeiana Henry, Standishi, Stella, or Vesta can scarcely ever become too plentiful. Some of the double-flowered kinds are also very handsome when well established, especially Lucie Lemoine or Mrs. Van Houtte, and I know a fine old specimen of C. Sieboldi that is a picture every autumn when covered

quite easy to root their branches by layering them under a large flattish stone, and plants so propagated are the best, albeit the process is a slow one. On light and warm sandy or gravelly soils these plants enjoy a top-dressing or mulching of short, well-decomposed manure every spring, or manure-water may be applied with advantage after growth has begun. B.

TRANSPLANTING RHODODENDRONS.

This is the best time of the whole year for planting Rhododendrons. The plants commence to grow at once, if proper care is taken of them after planting. When autumn planting is practised the roots remain practically inactive several months, and when they become soddened with rains they are much more likely to be injured by frost. Not that there is any likelihood of frost ever killing a Rhododendron, but it may receive such a check that little progress is made for a season or two; but where the planting is deferred until the spring, none of these risks are experienced. Rhododendrons will grow most luxuriantly in the natural soil in some districts, even where no peat is to be found,

quantity of foliage is diminished, this has an effect upon the maturation of the growth. Com-manure is a capital stimulant for plants that do not make a sufficiency of growth. Lightly scratch the surface, and lay on a 2 inch covering of freshly-gathered manure. As this decays it mixes with the soil. The manurial effects are washed down to the roots. S. P.

The White-flowered Wistaria.—One rarely sees this beautiful climber, although the blue-flowered type, *W. elaeagnis*, is common. The white variety is like it in everything except the flowers, which are pure-white, in delicate contrast to the species, and the two might be planted together with happy effect. The variety is a climber well worth growing, but it is not common as yet. A variety I sometimes see mentioned in catalogues is the double; but it is a poor thing—double-flowered, it is true, but not of the slightest beauty or value. Wistarias like a sunny spot and a light soil. There are other varieties of the Wistaria, but the white is the most beautiful.—C. T.

Pyrus japonica virginialis.—Those who prefer purity in the white will give the preference to this fine variety over that of the common white, because of the large size, fine shape, and snowy whiteness of the flowers. But both are remarkably good; the creamy tint of the ordinary white variety goes well with the red as with the pure white. All are blooming freely in the open air just now, and any position appears to suit them—the most preferable from east, southwards to west. I do not think the Pyruses are sufficiently appreciated as plants in pots for flowering in a cold-house in early spring. It is in this way I grow virginialis, and it is remarkable how long it remains in flower, and how successfully it blooms. In this respect it contrasts most favourably with the fleeting character of *Pyrus Pissardi*.—D.

Berberis Darwini—Often as I have urged the usefulness and beauty of this Barberry as a plant for walls, especially for comparatively dwarf ones, I am unable to resist again mentioning it, for on my cottage at the present time it is truly lovely—notably, a plant encircling a bow window having a west aspect. In addition to being trained a good width under and around it, a single stem has been led up each of the grey stone mullions of the window and then festooned along the top. This being in full bloom is a pretty and rather unusual sight. To prevent the undue obstruction of light, these shoots (especially on the mullions) are after flowering spur-pruned. By so doing we certainly lose the bluish-purple berries, but to make amends for such, a few growths of the Flame-flower (*Tropaeolum speciosum*) are led up these shoots. These in autumn bloom profusely and also berry, so I think the loss of the Barberry berries, in this instance, is amply and interestingly replaced. Neither does this arrangement appear to be in the least detrimental to the Barberry, for it is annually a mass of bloom.—R.

Chinese Plum (*Prunus triloba*)—This is a charming spring-flowering shrub. The flowers, produced with great profusion in April, are individually quite a little rosette of delicate pink. It may be grown as a bush, but it is best as a wall climber, and in many small gardens spare can be found for this shrub, which is perfectly hardy, not troublesome to grow in any way, but likes sunshine. The flowers appear before the leaves and one gets a mass of bloom. The season for planting has gone, but it is one of those good things that should be made note of for getting early next autumn. In many small gardens shrubs of a common kind, usually evergreens, are planted in a way that leads one to think nothing else is available. The Chinese Plum is seldom seen, although very free, hardy, and covered with pretty flowers in the spring.—C. T.

8551.—**Aucuba japonica**—The *Aucuba japonica* is often erroneously called a Variegated Laurel. To obtain berries you must introduce a male plant or get pollen from a male plant and dust it over the common variety of japonicum when the latter is in blossom.—E. H.

This is sometimes termed the Variegated Laurel, and is one of the easiest garden shrubs to cultivate. The old variety with mottled leaves is the female plant, and was grown for about sixty years in England without bearing a single berry. The green-leaved variety, introduced

White Clematis on a fence.

with its purple-centred rosettes of a soft straw colour. Other good single kinds are: Miss Bateman, Mrs. Bateman, Othello, Lord Londesborough, Fair Rosamond, and Fairy Queen, and a good double-flowered variety of a rich purple colour is the well-known Countess of Lovelace. As wall or trellis climbers all the best varieties deserve notice, but it is necessary to be careful in planting, or failures will be numerous. Good strong plants in pots are best to begin with, and these should be planted out in the position selected for them after all danger of severe frosts is past, say the middle of May. In obtaining these plants, one should be careful to find out if they have been lifted from open-air plunging-beds, or whether they have just been taken out of a warm greenhouse temperature. A practised eye will see this in a moment, but an amateur might not notice the difference, and in the latter case injury to the plants or actual loss would follow their being at once planted out-of-doors before May or June. Another drawback is that nearly all these plants are grafted on roots of wild or common kinds, and the union is often so slight that they are easily broken by a touch or in transit. Wherever plants of the best sorts are established it is

but a sandy loam, while in another place where the least suspicion of lime is present, even in the form of chalk, much expense must be incurred to obtain success with these shrubs. Soil impregnated with lime in any form is fatal to the existence of Rhododendrons—they will not live in it, let alone flourish. Peat or bog soil then has to be introduced, at least 2 feet in depth, for the roots. It is surprising what a number of years Rhododendrons will succeed by digging out a hole, and simply filling it with suitable material, even if such soil does not extend more than 6 inches beyond the roots. Directly the roots reach the outside of the prepared compost and come in contact with the natural soil which is objectionable, a change takes place in the colour of the leaves, these turning pale, and not making free growth. I have grown Rhododendrons under such circumstances as these for many years by adding fresh material for the roots, say 6 inches further all round every six years, and with fair success. I find where the plants are exposed to the full influence of sun and under such conditions of soil a greater quantity of bloom-trusses are produced and less growth, owing to the shoots not being so thoroughly ripened. Consequently upon less vigour and more exposure, all the

some thirty-five years ago, was the male plant; and when it was planted in juxtaposition to the old established variety a profusion of berries was the result. These berries vegetate very freely, and the produce of them has given many fine varieties.—J. D. E.

— I think I have heard this shrub called variegated Laurel. If you want it to bear berries you must get a male plant, the leaves of which are not blotched and are of a prettier outline than the female shrub, their margins being decorated more after the character of a Holly-leaf; plant the male near the female, and the blue-berries will do the rest of the work for you (they like evil-smelling flowers), and you will have an abundance of berries in the autumn.—A. G. SERRA.

3564.—**Magnolias not flowering.**—There is an inferior form of *Magnolia grandiflora*, which grows vigorously but rarely flowers. No doubt your plants are of this variety, and I regret I cannot tell you what to do with them to make them flower. The better form, that known as the Exmouth variety, which does so well as a standard in many gardens in Devonshire, has broader and thicker foliage, and a good part of the underside of the leaves is covered with a russet kind of down.—J. C. C.

3572.—**Jasminum nudiflorum.**—If the plant is judiciously cut back now the young growths made during the summer will flower next winter, but of course the centre of the tree will be comparatively bare for two or three years, and if you want a really neat, well-trained specimen, the best way would be to root it up and plant a fresh one. This charming subject should always be pruned directly the flowers are over, and then the young shoots will bloom the following winter. Merely thin out any weak or exhausted wood.—B. C. R.

— As this *Jasminum* flowers on the young wood, spring is the proper time to prune: the earlier the better in order to get the young wood ripened. It is quite late enough now to do it.—E. H.

OUTDOOR PLANTS,

HARDY HERBACEOUS LOBELIAS.

The hardy perennial *Lobelia*s, of which *L. splendens* and *L. siphilitica* may be taken as types, are amongst the most beautiful and useful of autumn flowers. Although fairly hardy, they are very impatient of excessive moisture, and in most districts require protection during winter. This may be done by placing ashes in the shape of a cone over the crowns, or lifting and storing in a dry shed or frame. The latter method, though perhaps more troublesome, is safer, and in every way more satisfactory, as the plants are always under control, and easier to get at for propagation in spring. By storing the roots in frames they begin to grow earlier, and where large stocks are required it is most convenient. Although impatient of moisture during the resting period, they revel in it when in active growth, and where beds can be prepared in the vicinity of lakes or streams, better results will be obtained than in the mixed border or flower-beds. In propagating in early spring they can be divided into single crowns, and these, potted on, soon form sturdy plants ready to plant out on the approach of warm weather. They thrive best in a free vegetable soil, and like plenty of sun, unless in the case of *L. cardinalis*, which I find thrives best in a partially shaded bed.

L. CARDINALIS.—The true plant is one of the rarest, though one of the brightest of the genus. The brilliant effect produced in autumn by tufts of this species well repay any trouble it may give, for though by no means fastidious, the difficulty of growing it well in small gardens in the absence of shade and moisture is very great. It is a real bog-loving plant, being found in wet ground in Brunswick, Florida, and the borders of Texas. It may be described as the least hardy of those mentioned here, and on this account is often considered annual or biennial. It is, however, a true perennial, although maybe a short-lived one, and should be frequently raised from seed to make sure of keeping up the stock. This species is not so liable to disease as the *splendens* varieties, and may be kept a little damper during the resting period. Grown on an ordinary border, it invariably has a weak, stunted appearance, but in a free, rich soil in a shady position, and well supplied with moisture, I have often seen it 3 feet to 4 feet high, and flowering very profusely. The flowers are of the brightest and most vivid scarlet, and

fully effective, and as they last a long time in perfection it well deserves care and attention. So far as I know, there are no varieties of this species in cultivation. Dr. Gray mentions it varying to rose colour and even white, but this, it seems, is rare, and I have never seen anything but the scarlet form. Parkinson mentions it as "cherished in our garden in 1620," and gives it as "growing near the River of Canada, where the French plantation in America

The Scarlet Lobelia (*Lobelia cardinalis*).

is coated." It differs from all the other species in its bright scarlet flowers and broad serrated leaves. The annexed illustration gives some idea of the effect of a single clump of this grand species.

L. HYBRIDA of gardens, but also called *Milleri* and *L. fulgens* var. *violacea*, appears to be a hybrid between *L. splendens* and *L. siphilitica*, though of this we are uncertain. Its fine rich violet-purple flowers mark it out for special distinction. It is invaluable for grouping in the flower garden or mixed border, and is one of the hardiest of the hardy *Lobelia*s. It may be left out during winter with perfect safety, and can be lifted, divided, and replanted in spring without trouble. The leaves are almost as broad as those of *L. cardinalis*, glandular, hairy, and with the long sepals and hairs of *L. siphilitica*.

L. SPLENDENS.—This species is also called *L. fulgens*. Next to *L. siphilitica*, it is the most prolific of varieties of all the *Lobelia*s, Queen Victoria, Sir R. Napier, Rob Roy, and a host of others having been obtained from it by florists. These vary in colour and habit very much, and as they are all robust, free-flowering plants, they are indispensable in the autumn garden, where they give such striking effects until cut down by early frosts. *L. splendens* differs from the others by its much narrower leaves, almost glabrous, and all but the lower sessile or stem-clasping. It will be found a really good border plant and harder than *L. cardinalis*. The variety *igoea* has broader leaves and larger flowers.

L. SIPHILITICA.—An extremely variable species, and one of the most useful autumn plants we possess. It is very popular for grouping, and proves so hardy and robust in the soils that it might with advantage be

introduced into the wild garden or the mixed shrubbery. It may be managed much in the same way as *L. hybrida*. It will be found to stand the winter well, and as it is prolific in varieties of all shades of violet and purple, varying to rose and white, it cannot fail to become a favourite. North America. Flowering from July to September.

L. TURPA belongs to an entirely different set. It is often called *Tupa Fuelli*, and although a native of Chili, will be found to stand well in the south with such protection as may be afforded with sifted ashes, gravel, or other loose material. It is best, however, against a south wall or in front of a house, and when doing well often attains a height of 6 feet to 8 feet. The flowers are large, brick-red, and produced in large racemes, and the leaves are broad and woolly. It flowers from July to September. *L. Cavanillesii* is said to be manageable to the same treatment as above, but I have not tried it out-of-doors. K.

A note on Primroses.—The great thing in getting good garden Primroses is to select strong colours, not washy or weak shades, very poor in the beds or borders. If good seed is sown, selected from a carefully-tended strain, many bright colours will occur, which should be set apart, and the others destroyed. One sees a large number of worthless varieties, especially washed-out shades of red, which are positively on eyesores. Large, bold, handsome flowers, such as one gets in the beautiful *Manstead* Primroses, are the kind to make an effect in the garden—clear, brilliant crimson, pure white, yellow and allied self colours, very bright and attractive. A poor lot of Primroses is very objectionable, the colours appearing so dull and uninteresting against the beautiful self-coloured kinds that brighten the garden with their flowers.—C. T.

Saxifraga sancta—For many years I wondered why this deep, almost orange-yellow-flowered species should remain comparatively unnoticed. It is always a neat, deep green, shining-foliaged plant, and when in flower in March and April it strikes one as being much brighter than some of the favourite yellows that preceded it by about a month, such as *luteo-purpurea*, *Malyi*, *arctoides*, and the yellow *Burseriana*. I am aware of one objection to it; it has the reputation of being a shy bloomer. You get over this, however, by simply leaving your plants undisturbed beyond a little top-dressing. It should be allowed to expand into tufts as big as a man's hat. A friend wrote me last season from Grange-over-Sands that "a clump the size of a large mole-hill is one of the greatest novelties I have met with. When crowded all over with bright yellow flowers it gave a striking effect on a limestone rockery."—W.

Dwarf Dahlias.—The various forms of dwarf Dahlias are very useful when cultivated so that their flowering period may begin soon after midsummer. Cactus varieties seem to be the most popular at present. To have these and others early (they are now at end of April showing flower-buds), I plant the roots in boxes during February, slightly covering with soil and placing in warmth. They soon start into growth. They are divided when the shoots have started a few inches. If young stock is desired, cuttings are taken off and rooted in 2½-inch pots plunged on bottom-heat. They are grown on in the boxes till May, and then are well prepared by judicious exposure till the end of the month or early in June, when they are planted out in rich ground, and well watered and staked. They begin to open their flowers soon after, and continue blooming till frost puts an end to their usefulness. In good seasons they supply out flowers to the end of October. I do not bold with the system of growing Dahlias to the end of August before they flower, as they sometimes become disfigured during the month of September from early frost.—M.

3553.—**Perennials for beds**—One of the best perennials for producing abundances of showy flowers is the *Pentstemon*. Next to that I should recommend *Antirrhinum*, then *Campanula*, *Pyrethrum*, *Phlox*, *Gaillardia*, *Aquilegia* (including *A. californica*), *Ranunculus acuminatus*, *plenus*, *Iris*, *Papaver*, *Aconitum*, and *Dianthus*. Most of the above have endless lovely varieties, and if you fill in between with

Roses and Pansies your garden will be gay through the summer months, though I personally prefer greater variety, to last from early spring to late autumn.—A. G. BUTLER.

— *Gaillardia grandiflora maxima*, or *Hybride* (orange and red), *Anemone japonica* (white and red), *Chrysanthemum maximum* (white), and *Fuchsia globosa*. If covered with mounds of ashes in winter, the roots will be safe; or the plants may be lifted and stored in boxes, and planted out again in spring. *Salvia patens* roots lifted in autumn and stored in sand may be planted out again in spring. There may also be several beds of Tufted Pansies. *Antirrhinum* in assorted colours, such as white, yellow, and red, make very bright and showy beds; and if the seeds are cut off they will flower all summer. *Gemm coccineum plenum* (scarlet), and a bed or two of Iceland Poppies will be showy and fairly lasting. *Pentstemon* make beautiful masses; they are not quite hardy, but if cuttings are taken in autumn, and planted in a cold frame, they will soon make strong plants when put out in spring. Why not try a bed or two of Tea Roses and Perpetual Carnations?—E. H.

— The following are all showy and froo-flowering objects. I append their approximate of growth, also time they flower. *Anemone japonica alba*, 2 foot to 3 feet high, white, September; *Campanula persicifolia*, blue, 2 feet, June and July; *C. carpatina fl. pl.*, white, 2 feet, July; *Chelone barbata*, 2 foot, red, July and August; *Coreopsis lanceolata*, yellow, 2 feet, July; *Chrysanthemum maximum*, white, 1 foot 6 inches, August; *Rudbeckia Newmani*, orange, black centre, 1 foot 6 inches, September; *Helenium pumilum*, yellow, 15 inches, August; *Lychnis vicaria splendens fl. pl.*, 1 foot, magenta, May; *Stenactis speciosa*, magenta, 2 feet 2 inches, June, July and August; *Bupthalmum salicifolium*, yellow, 2 feet, July; *Gaillardia grandiflora*, orange and yellow, 1 foot 2 inches, July.—S. P.

3547.—**Ten-week Stocks and China Asters.**—Asters are often planted outside in a bed, lifted with balls of earth, and potted late in summer. But the foliage is better when, after being pricked off thinly in rich soil in boxes to get strong, they are placed in 5-inch pots and plunged in the pots outside in a bed of Coconut-fibre or old leaf-mould. If well grown, one plant is enough in a pot. Stocks must be grown in pots all through, or they lose all their leaves. Give liquid-manure as soon as the plants get strong enough to use it.—E. H.

— If the plants are not already growing no time should be lost in sowing the seed thinly in sandy soil in a gentle warmth if possible. When the plants are 2 inches high prepare a sufficient number of pots by first placing half-a-dozen crocks each about the size of a penny-piece at the bottom; over these place a few rough leaves, filling up the pots with a compost of three parts loam to one part of partly decayed horse-manure, pressing it firmly into the pots. Prick into the soil up to the seed-leaves three plants of Stocks and four of Asters, placing them within an inch of the rim of the pot. Stand the pots in a cold frame until the plants are secure from frost, then put out-of-doors in a sunny spot.—S. P.

3544.—**Narcissus flowers dying off.**—All the members of this family need to be growing in the full sunlight to enable the bulbs to ripen thoroughly to give a full crop of flower the next year. Want of maturity, owing to the unfavourable position, is the cause of the flowers dying off. When the foliage changes colour, dig up the roots, and divide them if several bulbs are growing together, and plant them 4 inches deep in any sunny spot.—S. P.

3550.—**Selection of Dahlias.**—Six of the finest Pompons are: *Iolanthe* (orange), *Grace* (orange), *Geo. Brinckman* (white), *Isault* (yellow), *Vivid* (orange-scarlet), and *Don Juan* (maroon). Six show varieties: *W. E. Gladstone* (rose-pink), *Thos. Hobbs* (magenta), *W. H. Williams* (scarlet), *Gloire de Lyon* (white), *Harrison Weir* (yellow), and *Geo. Rawlings* (maroon, nr *H. Turner* (flesh-white). Six fancy: *M. & C. Campbell* (buff), *Peacock* (maroon, tipped white), *Rev. J. B. Canim* (yellow, tipped red), *Major Bartlett* (orange). *Comedian* (orange and crimson), and *Lottie Eckford* (white and purple). Six best Cactus: *Parthea*, *Mrs. Douglas*, *Lady Marcham*, *Duke*

of *Clarence*, *Beauty of Arundel*, and *Juarez*. *Viridiflora* is a semi-Cactus variety, and not a Pompon.—B. C. R.

— Six is a small collection of Pompon varieties, but I should give preference to *Ariel*, the flowers of good form, the colour of a distinct orange-buff shade; *Darkness*, very deep maroon, a very attractive variety for its depth of colouring; *Fairy Tales*, pale-primrose, the flowers very neat and pleasing; *Little Ethel*, white, with the petals tipped with purple; *Vivid*, orange-scarlet; and *White Aster*, the flowers pure white and excellent for cutting. I do not think that you would show *D. viridiflora* in a collection of Pompon kinds, but the flowers are not sufficiently interesting scarcely to go in a show box of Pompon varieties. You should choose some brighter flower. The "*Green Dahlia*" is all right in a miscellaneous collection, and has a certain interest from its distinctive green flowers. Fine show Dahlias are the following, but of course, as this section is of large extent, it is a matter of taste in some degree. You cannot do wrong by selecting *Celostat*, the colour chocolate, on a fawn shade; *Glowworm*, orange-scarlet; *Mrs. Gladstone*, soft delicate blush, without question the best of the light-coloured varieties; *J. T. West*, yellow, topped with purple; *Eclipse*, orange-scarlet, and *R. T. Rawleigh*, rich-yellow. Of the fancy kinds, select *Duchesse of Albany*, orange, striped with crimson; *Fanny Stuart*, red, with white tips to the petals; *Frank Pearce*, rose, with stripes of crimson; *Lottie Eckford*, white, with purple stripes; *Mrs. Saunders*, yellow, the petals tipped with white; and *Pelican*, white, with purple stripes. The best six Cactus kinds are *Amphion*, chrome-yellow in colour, with a tint of cherry shade in it; *Henry Patrick*, of the purest white; *Juarez*, scarlet; *Mrs. Hawkins*, sulphur colour, with a lighter tone towards the margin of the petals;

FERNS.

FERNS FOR GROWING IN HANGING-BASKETS.

THIS mode of culture for Ferns has much to recommend it, inasmuch as with a suitable selection for respective kinds of houses Ferns are, on the whole, as well or better adapted for the purpose than any other description of plant with ornamental foliage. Lofty conservatories of an ornamental character are excellent places for displaying hanging-baskets to advantage. Considering that sufficient room for flowering plants can be found upon stages or other positions at a lower level, it is on the whole considerably better to depend upon the baskets being filled with plants that will remain of permanent interest. The best position for hanging-baskets is over the pathways, so as to avoid any drip upon plants beneath them. These may be suspended in two ways with advantage—either by means of slender or sufficiently strong chains or by wire rope running through pulleys. This latter is a convenient method for watering without the use of steps, which have to be used in the other instance. A very good time for watering hanging-baskets is at nightfall, the object being to avoid any drip during the day-time; when this is not suitable the early morning is the next best time. The majority of Ferns in hanging-baskets require but little shade. Where this is the case more water will be found necessary; in fact, Ferns in baskets will, in comparison with those in pots, absorb a deal more moisture; hence, good attention is requisite upon this point. In making up baskets of hanging Ferns it is far better to select a tolerably good and strong plant rather than two or three weaker ones. The sides of the basket should be lined with Sphagnum Moss to hold the soil as well as to retain moisture around the

Hanging-basket of Ferns.

Parthea, salmon, shot with red, and *Professor Baldwin*, orange-scarlet, true shape of the true Cactus character.—C. T.

3507.—**Rats and Water Lilies.**—I should advise "D. H." to wage war against the rats. They will not hurt the plants, but will damage the blooms. I am killing them this season along the banks of a lake just planted with Lilies. It is not usual to have much coniferoid growth where there is a constant flow of water unless it be sluggish. I should try some ducks or other water fowl, but not Moorhens, as they damage the flowers.—A. H.

Sufficient room should be allowed for watering, keeping the crown of the plant in a slight hollow. Around the sides some Selaginella should be pricked in; this will soon take root if the baskets be kept for a short time in a humid atmosphere, and at the same time be an assistance to the Fern itself. The baskets are most durable when made of wire, afterwards galvanised; these may be of various sizes, but those unduly small do not give sufficient room for soil. The tops of the baskets should be the widest part; plain baskets are just as good as those of an ornamental character, bearing in mind that the Ferns are the real ornaments—

not the receptacles. Ornamental baskets of rustic make look very well, but these when made of wood do not last so long in good condition. Those made of pottery are better, but are, of course, heavier; hence wire-baskets are the most suitable for the purpose. The soil for the majority of Ferns in baskets should be about equal proportions of fibrous peat and loam with sand. For an ordinary conservatory that is kept at about the temperature of a greenhouse with free ventilation the following are good kinds to grow—viz: *Asplenium adnigrum*, *Davallia canaliculata*, *Arisaema assimilabile*, *Leucostictum palmatum*, *Nephrolepis linguis*, *Platyterium albidum*, and *Woodsia radicans*, the last for large baskets. In a temperate-house the following will do well, viz., *Oniophlebium subauriculatum*, *Adiantum amabile* (one of the best of all), *A. cuneatum*, *Davallia elegans*, *D. filix-mas*, *Lygodium scandens*, and *Nephrolepis exaltata*. For a stove temperature the following may be added to the foregoing selection—viz., *Asplenium loegisimum*, *Davallia teenifolia*, *Vectichia*, *Nephrolepis davallioides furcata*, *Adiantum coelestinum*, *Gymnogramma schizophylla gloriosa*, *Davallia bullata*, and *D. Mooriana*, the last for baskets of extra size. *Adiantum farleyense*, where it does not succeed so well as one could wish, should also be tried suspended from the roof in a stove; this treated it often thrives remarkably well. About the present is a very good time for making up Fern baskets. That of which an illustration is now given is a good example. P.

3511—Ferns for a rockwork.—You may have a very charming selection of Ferns for the rockery, or in a shady, moist place the Lady Ferns, *Blechnums*, Hart's-tongue, and the finer kinds of *Asplenium* will grow with vigour, also the *Osmundas*. I like the varieties of the Common *Blechnum Spicatum*, as they soon form handsome tufts, the fronds of a deep green colour. There comes a great number of ferns, from crispum, which has elegantly-crested fronds, to those of a simpler character. The Shield Ferns, *Aspidium aculeatum* or *Polyetichum angulare* are very pleasing, when growing in a moist, shady corner, and there is a wealth of beauty in the *Osmunda*, *O. regalis* attaining considerable height, and presenting a bold, robust, and handsome aspect. Then you may get the North American *O. cinnamomea* and the dwarf *O. Claytoniana*, which has fronds of a very bright colour. The Ostrich Ferns are also of value, particularly *Struthiopteris germanica* and the elegant *S. pennsylvanica*, which thrive well in a moist, shady spot. You will find this selection sufficient for your rockwork where there is moisture and shade, and very easy to grow in a good deep soil.—C. T.

ROSES,

ROSE NOTES.

This is a very busy time for the rosarian both inside and out. Roses under glass are in full growth and are constantly demanding attention if one is to keep them in good health. Whether the plants have been forced since Christmas or only allowed to come on naturally in a cool-house, there is ample work to attend to. It is during the changeable weather of this month that Roses are so often spoilt by the amateur and least experienced gardeners. The sun now often shines brightly for an hour or so at a time, and it becomes a hard matter to ventilate the house judiciously. There would be much less difficulty about this if the wind and air were not so keen. An hour of sunshine and the temperature rises with a bound, to fall again almost as suddenly when the sun is behind a cloud. I see very little fire-heat indeed during this month, generally letting the fires out early in the morning and lighting up again about six o'clock at night. By shutting the houses up early in the afternoon and damping down the walls and walks slightly, one can secure a sufficiently high temperature until the pipes are able to replace it. It is less expensive, both in time and fuel, to let the fires out during the daytime if one can manage enough heat by careful ventilation. When the house is kept up to the maximum temperature required by the use of fire-heat, it quickly gets too hot when the sun comes through the pan-

hour or two. It is also quite natural for the house to be colder in the early morning than at any other time during the twenty-four hours, and the slight warmth given by stirring the fire up and then allowing it to burn out, is generally quite sufficient for Roses during the months of April and May. Slight shading will be very beneficial, and as this can easily be applied so as to merely break the glare of the sun, I find it much better to have it done in time. My plan is to mix a little whitening with skim milk, and apply this with a brush. A very thin solution will suffice during these two months, and will be found a great help in maintaining an even temperature. Much of the solar heat will be secured without the burning effect the sun has when shining through clear glass. Another advantage is the freedom with which you may use the syringes without fear of burning the young growth, and a gentle syringing during the hottest part of a bright day helps the plants a great deal, as well as moderates the temperature. When the glass is slightly shaded, it is not necessary to admit air so freely during bright weather, and this also is a great gain, because the outside air during these months is often very keen and will bring on mildew in an astonishingly short time. While the Roses are making healthy growths of considerable strength is the best time to afford them some assistance in the way of liquid-manure. It is altogether wrong to give stimulents to weakly growing, comparatively speaking dormant plants. Yet we often see this done, under the mistaken impression that the weaker subject is the one that requires it most. The exact opposite is the more correct treatment, as it is only the stronger growing plants which are able to utilise any liquid-manures to advantage. Manure-water is very apt to make the soil sour and stagnant, unless the roots of the plants are sufficiently vigorous to assimilate such food quickly. Both for healthy and weakly-growing Roses the ammonia arising from an occasional

DAMPING DOWN OF LIQUID-MANURE is very beneficial. Such assistance as this will often give the necessary impetus towards a healthy and more vigorous growth. I also find that the ammonia is useful in checking insects, and never consider that manure-water is wasted when used in this manner. Do not be afraid to let the temperature rise as high as 80 degs. or 85 degs. Fahr. in preference to admitting any keen air upon a bright day. Provided the glass has been ever so slightly shaded, you may moderate the heat and ease the plants by a gentle syringing overhead; in either case, shaded or not, you can assist them by damping down the walks and surface-soil as much as possible without sprinkling the foliage. Clear, soft water will be necessary for such syringing, and care must be taken that it is not used too cold. I would recommend that it never be colder than 65 degs. As I have frequently advised, cold air and drought at the roots must be carefully avoided, or mildew is pretty sure to attack the plants. Nothing can be more injurious than this disease, and too much care cannot be taken in avoiding it. The frequent use of a weak solution of some reliable insecticide is the finest antidote that I know of, and this will always prevent the mildew from getting so firm a hold of the plants as would otherwise be the case. Sometimes the air comes in through a chink in the weedwork or bricks, also through the corner of a broken square of glass; any foliage near to these places is often attacked with this fungoid disease. Such foliage should be removed at once and destroyed. It will also be well to stop up the holes in some way. Roses are partial to fresh air, but it must never be colder than they have been used to, nor must it come to them in the form of a draught. Sooner than this, I would keep the house entirely closed. There is also a great deal to be done in the outside rosery during April and May. The early part of April is the best month for pruning Roses in northern or cold and exposed situations, and is also the best time for the more tender Tea-scented and Noisette varieties even in warm and sheltered places, while the end of April is quite soon enough for this class if the situation be in any way exposed. Having pruned the plants, give the surface ground a light forking over again, and as soon as the eyes are pushing into growth of about 2 inches to 4 inches take the first reasonable opportunity to water the

hee among the plants. This will check any seedling weeds, and at the same time assist the plants. Soon after the plants have reached this stage—which will generally be about the end of May—they are likely to be troubled with the Rose-maggot or caterpillar. These must be hand-picked as soon as they appear. Many birds will assist in clearing off these enemies, and I have often watched the common house sparrow eating them. This bird is a great nuisance in many ways, but he has his good qualities as far as the rosarian is concerned. The strange thing to me is, that when these birds have tasted the maggots they are positively ravenous after them, and yet in some seasons they do not seem to eat them at all. R.

CLIMBING ROSES AND THEIR USES.

WHAT can be more beautiful than an Ayrshire or Evergreen Rose scrambling up the stem of some old tree, which is probably bare of branches for the first 10 feet or 12 feet from the ground-line, although its lofty head is a fine feature on the outskirts of a lawn or shrubbery? Deftly and rapidly these Roses twine and wind themselves around the rugged trunk till they reach the branches above, where, spreading and bending downwards, the clusters of flowers gracefully intermingle with leaves and branches. Climbing Roses are equally well adapted for trailing over arcades, painted iron arches, arbours, and rustic temples. For the purposes just indicated, the Ayrshire, Evergreen, and Multiflora Roses are the best, while Gloire de Dijon and Lamarque both do well on painted iron arches and trellises. They grow vigorously when well fed, often making shoots 10 feet to 12 feet long in one season. They are very hardy, and when fairly established flower most abundantly. For low fences the Hybrid China, the Hybrid Bourbon, and the strongest-growing Hybrid Perpetuals may be used; and if a wall with a south aspect requires to be covered, whether high or low, some few of the Noisette, Tea-scented, and Bankian Roses are the very best kinds that can be planted. The general management of climbing Roses is familiar to every Rose-grower. The Bankian Rose alone requires special treatment. It is common to hear of this Rose growing freely, but flowering sparingly. This is usually due to the system of pruning, very little of the latter being necessary. The gross shoots should be stepped during the growing season, and the thin wiry shoots removed early in the spring. The aim should be to obtain and preserve a goodly number of moderate-sized, well-ripened shoots, for it is such, and each only, that produce flowers. T.

ROSES ON WALLS.

ROSES may be grown almost equally well on walls at every point of the compass under favourable conditions of soil, selection, and culture. With the single exception of due north in bleak, unsheltered localities, almost all Tea and other Roses may be successfully grown on east, west, or north or south walls. The chief differences will be in the time of blooming rather than in the quality of the blooms, with, perhaps, the two exceptions of Cloth of Gold and Maréchal Niel. A west wall or fence will produce more perfect Roses than a south one, while the commoner Teas, such as Gloire de Dijon and Homère, will often come more perfect on a north than on a south wall. And then the variety of aspects produces such a charming succession of the same Roses throughout the year. It is always worth while growing a few Maréchal Niels on a north wall for the sake of obtaining some fine flowers in the late autumn. It is easy to protect such tender Roses as the Maréchal Niel, Lamarque, Triomphe de Rennes, Niphetos and others on north or east walls in winter, and gather such flowers as can seldom be cut from southern or western aspects. Of course, the earliest Roses from the open will be gathered from the warmest walls, but it by no means follows that the finest Roses will be gathered from the sunniest aspects. After or even before midsummer the finest Teas and other Roses are often gathered from the coolest aspects. It is, in fact, quite a relief to turn from the panting heat of the midday sun's broad glare in June to pick Tea Roses from the deep shadow of a north or the partial shade of an east

wall or fence. Such Roses as Gloire de Dijon from north walls put on new colours and more delicate forms, and are virtually new Roses as well as old favourites at new seasons and in unexpected places. Hence the season of most practical moment is that all aspects may prove best for Roses according to times and circumstances, and each will contribute to the greatest of all Rose charms, continuous supply. F.

Rose "Reine Marie Henriette" under glass.—It is only towards autumn that the deep colour of the flowers of this Rose is seen when grown in the open air, and as it is not so free-flowering at that time as in the early summer months, it is not considered a first-class Red Rose for outdoor culture. Under glass, however, it is always very highly coloured and forms one of the very best deep Red Roses we have. For early forcing there is probably no Red Rose superior to Reine Marie Henriette. It forms a particularly pleasing bud of a long and pointed shape, and each one opens into a good-sized flower, while it leaves nothing to be desired in its freedom of growth and flowering. This Rose may be treated exactly the same as Marechal Niel, and, generally speaking, it will give better results. The flowers are also a grand contrast in colour, and

out the plant altogether and replace with another. Oftentimes the second plant does well. All strong growers are liable to canker, but Marechal Niel is about the worst.—P. U.

— The Rose is attacked with canker and will do no more good. If the young shoots are below the cankered part it may be left for a season and see what comes of it. Fere des Jardins (yellow) and Niphetos (white) are good Roses under glass.—E. H.

3561.—Marechal Niel Rose in a conservatory.—Under the conditions which you describe I think the following will be your best plan. Cut away the whole of the wood that has already flowered, and so get rid of much of the green-fly at one sweep; at the same time, you will be doing quite correct in throwing the whole of the plant's strength and energy into the young wood for next season. I expect the reason the plant looks weakly is because the flowering shoots are now over and exhausted; the severe attack of green-fly which you mention would also tend to give the Rose a weak and sickly appearance. Why allow the Rose-aphis to gain any hold upon your plants? Under glass it is so simple to steer clear of this pest, and the remedies have frequently been given in GARDENING.—P. U.

— The growth of this Rose always gets weak when it is crowded. You had better cut

the man who may have to work it. The best staff I could obtain is that of an old hand taddy rake. It is used in the following manner: First, in taking hold of the shaft give the lawn a good sweep right and left with the bottom of the board, which will cause the worm-patches to fly and sweep evenly over the surface without being unsightly, but will be beneficial in helping the growth of the Grass. A man with practice will with ease take a drift 7 feet wide, and go over a large lawn in an hour or two. The same method of working the tool will answer well also for clearing off leaves from the lawn. Keep the handle well firm in the hand; and not allow the board to wobble down first on one side and then the other.—Geo. Woodcock.

THE EDELWEISS IN DEVON.

The specimen of the alpine Edelweiss of which I sent you a photograph, and which is represented in the annexed engraving, was planted four years ago in rather poor gritty soil in a crevice between lime rock and in a sloping position with a southern aspect. This evidently suits it best. The first year there were only two small blooms on the plant, next year it had six considerably larger, and last year there were

OUR READERS' ILLUSTRATIONS: The Edelweiss in a Devonshire garden. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. G. S. Symons, Chaddlewood, Plympton.

when grown under glass are altogether superior to those from plants cultivated in the open air. Our plants of this grand Rose make quite as strong and long growths as Marechal Niel, frequently throwing from four to seven or eight shoots 12 feet to 15 feet in length, and which flower with even more freedom than those of Marechal Niel. Where a good Red Rose is wanted, and sufficient room can be afforded, I can very strongly recommend Reine Marie Henriette, and, provided it is grown upon the long-rod system and treated the same as Marechal Niel, I am sure it will please all who give it a trial.—R.

3581.—Marechal Niel Rose in a greenhouse, &c—I should say from your description that the plant has that formidable and mysterious disease called "canker." If so, it would fully account for all you complain of. Stems often split with this disease, and one great authority informs me that the disease is caused by an overflow of sap eventually bursting the sap-vessels. No doubt this is the case in some instances, but in others it is caused by injury, followed by what seems to me to be a species of gangrene. If the young shoot you mention is below the split and cankered part, by all means cut away the remainder and leave the former to grow freely. If not, I would cut

away at once quite half of the branches right back to the stem, and shorten back most of the weak shoots on those branches left. If it is inconvenient to fumigate the conservatory for the purpose of destroying the green-fly you had better dissolve 2 oz. of soft-soap in 1 gallon of water, and the next day syringe the plant with the liquid when the house is closed at night.—J. C. C.

3332.—Worm-casts on lawns.—I have myself during many years been put to my wits' end in adopting various means to battle with this nuisance, and in most cases have failed. The weekly use of the roller makes all smooth for a few days, but still it leaves a patchy surface, and has the unneighbourly appearance of a person badly pitted with smallpox. The best remedy I have discovered is a very simple and cheap one—namely, procure a piece of deal board about 22 inches in length and 5 inches wide, and 1-inch thick. Then obtain a staff about 8 feet 6 inches in length, and adjust it as a handle in a slanting direction to the board, to which it should be screwed by two screws. The staff to be so adjusted that the handle end will be raised at an angle when fastened to the board of about 3 feet from the ground, or it can be adjusted higher or lower to suit the height of

eleven blooms, many of the flowers measuring from 12 inches to 14 inches in circumference round the outside edge of the points. Last year I tried some plants in another part of the rockery in richer soil and on the flat with the roots some little distance from the rock; there were numerous small blooms, but all were a dirty greyish-green in colour, a great contrast to the silvery foliage and snowy-white woollen bracts of the beautiful specimen you have engraved, and which were the admiration of all who visited our gardens during the last summer. The German name Edelweiss means "Noble White," with reference to its beautiful colour, and it is also called "Etoile du Glacier," (Star of the Glacier). When grown successfully it is certainly one of the most beautiful of alpine plants. G. S. SYMONS.

3546.—Getting rid of worms.—The lime-water was not strong enough, perhaps, or it was not applied in sufficient quantity to reach the larger worms, which lay deeper than the small ones. Place as much quick lime in water as will be taken up in suspension as it dissolves. When the lime in bulk settles to the bottom it is strong enough, or, what is more correct, the water will not contain more, therefore it is useless adding it.—S. P.

INDOOR PLANTS.

SCUTELLARIAS.

I HAVE received flowers of one of these pretty plants for a name from "A. Milne," and he says it has made his stove bright and gay since Christmas, which I do not doubt. As I find one of my readers taking a fancy to these plants, there are one or two kinds which I would recommend to his notice and advise him to add to his collection, these being much stronger growers than *S. Ventanati*, which he sends. They also produce a larger raceme of flowers, and these are much brighter in colour with longer tubes. These plants should be grown in an intermediate house, potted in loam, leaf-mould, peat, and sand, in about equal parts. They should have an abundant supply of water, and be pinched at the points pretty freely in order to make a succession of bloom. Treated in this manner, adding a little Clay's Fertiliser occasionally, these plants may nearly always be kept gay during the whole year. *S. Costaricensis*: This is a strong and robust growing plant for a Scutellaria, producing stout and long flowers which are set in loose racemes. The tube is a rich crimson-scarlet, and the limb of a bright orange-yellow. The flowers are admirable ornaments in the table glasses, mixed with Ferns and other blossoms. Indeed, all the species may so be used, but the plants should not be out too hard, so as to rob the plant-house of its colour; but the fact of cutting a head occasionally helps to set the plant growing, and thus maintains a succession of flower. *S. aurata*: In this we have a very different coloured species, and it is also robust in growth; it makes, however, dense racemes of bloom, which are light yellow in the tube and the limb orange-yellow. This is not quite such a continuous bloomer, but it flowers very freely. *S. Ventanati*: This is the most slender growing of the kinds here mentioned; but if not grown in too great a stove heat, and with a free circulation of air, it will continue to flower mostly all the season, producing racemes of a brilliant scarlet. It is a plant which is specially benefited by having its flower-spikes cut. *S. Moccisiana* is a superb kind, having very much the habit of *S. Costaricensis*, but it is not so strong in its growth, but it bears a splendid raceme of long tubular flowers, the tubes of which are a bright orange-scarlet, and the limb clear, rich yellow. No more beautiful flower can be cut for room decoration than a raceme from this species, and it produces its flowers very freely.

BLANDFORDIAS.

I AM very glad "S. S." has taken up this fine family of plants. The original one, *B. nobilis*, was introduced into this country about ninety years ago, and this is the species least seen now growing. The fact that these Blandfordias have been starved out of our gardens has caused *nobilis* and all the more recently-discovered kinds to be discarded by the majority of our plantmen, however; but anyone who has seen them doing well, as I saw them, say two years ago, when on a visit to Sir Trevor Lawrence's place, must be commended for endeavouring to grow them. "S. S." says he has got the kinds *nobilis*, *flammea*, and *Cunninghami*, and asks where he can procure more, and for some hints upon their cultivation? To answer the first part of the question, Mr. Bull and the Messrs. Veitch, of Chelsea, have been notorious for having introduced some of the most beautiful forms of Blandfordias, and you should by all means give them a trial, for in all probability they still retain some of these old favourites amongst their host of plants. Mr. Williams, of Holloway, too, has many plants, and I think also Mr. Cuthush, of Highgate, could supply some. Now for their management and cultivation, which may be said to be amongst the easiest imaginable. These plants have not been found at all in Northern or Western Australia, but they occur frequently in the hilly parts of this country from Tasmania to Queensland, growing in hoggly places on the hill sides, so that they always require to be potted in peat soil, and I have grown them well in a mixture of peat and loam, kept rather moist through the winter months, and when they begin to grow they like a large quantity of

water, so that good drainage is essential. They will succeed well under ordinary greenhouse treatment, and when they flower in the summer-time they present a magnificent sight, well deserving the attention of all. The following kinds I have grown and flowered, and I commend all to the attention of my readers.

B. nobilis.—This, although an old species, is a very desirable plant. It produces an erect stout stem, surmounted with a large terminal cluster of pendulous flowers, which are of a rich deep-orange, passing into bright yellow at the margins. *B. Cunninghami*: A magnificent species, which was discovered many years ago by the well-known Australian explorer, Allan Cunningham, and we have to thank the Messrs. Henderson, of the well-known nurseries in St. John's-wood, now no more, for its introduction to our gardens. It has a very stout erect scape, producing a large cluster of flowers some 2 inches long, which are deep rich orange-scarlet, becoming rich clear-yellow at the tips. *B. aurea*: This kind was introduced to cultivation by the Messrs. Veitch, of Chelsea, and it is at the present time perhaps the rarest kind of all the Blandfordias in cultivation, and its flowers are perhaps the broadest. They are borne just in the same manner as the other species, drooping, and of a clear bright-yellow. *B. flammea* is another lovely plant, which first came into notice from a plant that was grown in the Dublin gardens by Dr. Mackay. This is a very strong-growing plant, the flowers large, the colour being rich deep orange-scarlet, yellow at the tips. *B. flammea princeps*: The above plant had been doubtfully referred to some of the other species, but when Mr. Wm. Ball exhibited this plant before the Royal Horticultural Society in 1875 it was at once proclaimed to be a variety of *flammea*. Like all of the Blandfordias, it has drooping bell-shaped flowers, and the colours are much the same; but in this case, instead of being orange or orange-scarlet of some shade they are here of a rich, brilliant crimson, tipped with yellow. Some few other kinds are known, and I dare say, when the interior of Australia comes to be more explored, some more beautiful kinds may be found. J. J.

Dwarf Cannas.—The dwarf French Cannas are very charming, compact in growth, and vigorous. They are excellent to grow in pots for the greenhouse and conservatory. A very bright flower, and new too, is *Progression*, brilliant orange, barred with a reddish colour. It has very broad petals, and is an excellent kind. A good point about these French mixed Cannas is their fine leafage of good colour. A few other useful varieties are: *Admiral Courbet*, the flower yellow, with red spots; *Antoine Clément*, cherry-salmon, very useful and distinct; *Antoin Crory*, crimson; *Felix Crousse*, orange-red; *Jules Christien*, carmine crimson, the leafage deep-green; *Louise Christien*, yellow, spotted with red; *Paul Bert*, the flowers golden-amber, and the leaves of a fine deep colour; and *Ulrich Branner*, rich red, shaded with orange.—C. T.

Planting Freesia bulbs.—The earlier the bulbs are potted, the more freely they will start into growth. I pot mine about the middle of August, and every bulb starts in about six weeks from that time. If potting is deferred until September is well advanced, some of the bulbs will frequently remain dormant. The main point is to give them a good roasting in a sunny greenhouse, after the foliage dies off, and pot them before the warmth of summer is gone. Loam, with a liberal addition of leaf-soil, suits them best.—J. C. B.

Rhodanthee in pots.—Both the pink and white forms of the pretty Rhodanthee are largely grown for market. Of course, these are all in 4½-inch pots. The seed is sown in January for the first batch, the pots taking the places just previously occupied by Cyclamens. It seems to be an important element in the culture of these Everlastings that the soil should be very firm, so as to induce stout, stookey growth. Were the soil too light, the plants would be apt to run tall. Seed is sown thickly, very thickly in fact, as the grower holds that it is better to have the plants too thick than in many cases so thin that many pots have to be thrown aside as useless. However, it does not seem as if the plants are unduly crowded, judging by the admirable way in which they bloom so profusely

when about 10-inches high. The selling price is not considerable, but it is a paying one all the same.—D.

3559.—Climbers for a conservatory.—There are other fine Passifloras besides *P. princissa*, of which *P. Imperatrice Eugénie* and *P. quadrangularis* can be strongly recommended. Of others, beyond those you already have, *Mandevilla suevoles*, *Laelia grandisima*, *Rhynchospermum jasminoides*, *Bougainvillea glabra*, *Hoya carnea*, and, in a little shade, *Fuchsia* of almost any strong growing varieties, would all be suitable for such a structure and temperature. You might even try an *Allamanda* and a *Stephanotis* or two, as with plenty of heat and moisture during the summer both succeed admirably even where the temperature does not exceed that of an ordinary greenhouse in the winter.—B. C. R.

— *Clematis ledwici lobata* is a very good climber for a conservatory; it has white flowers, which are freely produced in spring. Roses love sunshine, but when in blossom a thin shade will keep the blooms fresher longer.—E. H.

3466.—Seedling Cyclamene.—Young plants should have for the next two months a constant temperature of not less than 60 degs. by day, with from 5 degs. to 10 degs. less at night. They should be shaded from hot sun, be kept nicely moist at the roots, and be sprinkled overhead in the morning in sunny weather. Early in July they should be put into 4½-inch pots, and from that time till October are best in a cold frame. If grown in an ordinary greenhouse temperature, keep them at the warmest end of the house and treat them as above mentioned.—J. C. B.

3580.—Carnations from cuttings.—It is not too early to take cuttings of Carnations; I began with the variety *Miss Jolliffe* and other *Tree-Carnations* in January, and continued to put them in until April. Cuttings of *Malmaison* may be put in as soon as they are ready; I had some ready in March, but had no time to put them in. They require a little bottom-heat and to be kept under close glass lights of some kind until roots are formed. It does not check the growth of the plants, nor does it in any way prevent the flowers from developing by cutting or slipping off the side-growths.—J. D. E.

— You are not likely to do very much good with cuttings so early in the year, the side shoots at present will be too seppy to root readily. Wait until August and prick your cuttings out into rich sandy soil, pressing the earth firmly round each one, then give a good watering and leave them alone.—A. G. Burton.

3555.—Palm-leave drying.—This is a very common fault; at least, among plants of this kind in both sitting-rooms and cool greenhouses. It is caused by want of warmth and moisture in the atmosphere, and would soon disappear (at least, as regards young leaves, though there is no remedy for those already affected) if the plant could be removed for a time to a warm and moist place, such as a stove or forcing-house. Watering is, however, a most important point, and either too much or too little would soon give rise to something of the kind. In a cool temperature water should only be given during the winter and early spring when the soil becomes really dry, so that it ought never to become even "moderately wet" at all—that is to say, during the season of rest. Snip off the brown parts with a pair of scissors, leaving the ends of the leaves still pointed.—B. C. R.

3573.—Bulbe from South Africa.—Those who have friends in South Africa frequently get bulbs or plants sent over in the same way, no doubt as this correspondent has done. Through a similar source a lot of Cape roots came into my hands a few years ago, containing most of those mentioned in this enquiry, and all I can say in their favour is the garden was not much the richer for it, chiefly for the reason that they arrived at an unaustralian time of year to start them. This correspondent is, however, more fortunate, as the present is a good time to commence to acclimatise them. Taking the subjects in the order named the *Watsonias* are perhaps the best known, and are supposed to be hardy if the bulbs are protected if left in the open ground, but in the West of England I could not get them to flower unless given greenhouse treatment. The *Antholyza* is not any hardier, but more easily managed, and blooms fairly well in pots. *Hemantus* (Blood-flower) is a brilliant subject when well grown. It requires careful greenhouse culture

to get the bulbs to flower satisfactorily. The *Cyrtanthus* is very similar to the *Amaryllis* in character, with large bulbs and thick fleshy leaves, but a difficult subject to get to flower. *Satyrium* (Frog Orchis) belong to the terrestrial Orchide, and the varieties I had to deal with did very well in a subterranean pit, but except that the flowers are curious they are not likely to reward you for the time and space they occupy. You must not lose any time in getting the whole of them potted. During the summer let them have the shelter of a frame, and in September remove all but the last mentioned to a greenhouse. Next year get them fresh potted early in March.—J. C. C.

3543.—Treatment of Fuchsias.—If you have the command of heat a temperature of 55 degs. to 60 degs. will start them into growth, and then by pinching they can be moulded into shape desired. Shift into larger pots as more space is required. Any good soil will do. Turfy loam and leaf mould, or very old manure, with some sharp sand, will grow them well. A moist atmosphere and a thin shade in bright sunshine during growth will be an advantage. The plants also should be kept near the glass.—E. H.

— If the plants have been neglected they will not do so well as those that have been properly cared for, but it is not easy to answer the question without more information. The size of the plants should have been stated, and what is the nature of the neglect. Fuchsias are really greenhouse plants, and I do not like a high, close atmosphere. Even small plants should be cut back a little before they start into growth; and when they have started just a little, shake them and repot into flower pots a size smaller, to be repotted again when they have made plenty of roots. They do best if placed in a light position in the greenhouse.—J. D. E.

— You do not give much information about the plants, but I presume that they have been allowed to run up and droop over, so as to look unsightly. Cut them down to a length of about 8 inches and tie them in with bast to a straight stick; keep somewhat dry until growth recommences, and then encourage with weak liquid manure twice a week. By the way, if they have been left in thumbs repot in 5-inch pots.—A. G. BULLOCK.

3529.—Orange tree from a pip.—If you shorten back the young Orange tree it will, of course, grow more bushy, and when grafted it should be cut back to encourage the graft to grow. When grafted it should be placed in a close frame till the union is complete; otherwise it will not succeed.—E. H.

3531.—Malmaison Carnations.—The Carnations have probably been forced too much, and this has caused the mal-formation; but it will happen occasionally, even when there has been no attempt to force them. It is not a disease at all, and the only way to prevent its occurrence is to grow the plants well, using good rich loam, and taking care that the leaves are kept free from green-fly and mildew. When the plants are in small flower pots it is a good plan to dip them in a mixture of soft-soapy-water and flowers of sulphur. This will destroy any mildew or fungoid growth as well as the green-fly. When Carnations are forced, especially at mid-winter, they should be placed up near the roof glass in the lightest possible position that can be obtained for them, and admit air as freely as possible, according to circumstances. If the insects inside the petals are thrips they are very troublesome, and make a sad mess of the flowers. The best way to get rid of these is to fumigate with Tobacco. The oldest and true *Souvenir de la Malmaison* is a beautiful bluish colour. There is a variety with pink flowers a sport from it. It is usually termed the *Pink Malmaison*. There is another sport with striped flowers, which is grown under the name of *Lady Middleton*. The crimson "*Malmaison*" is *Mme. A. Warocque*. There is no yellow *Malmaison*. I have no knowledge of the *Germanica Tree Carnations*. Are they different from the usual type of *Tree Carnations*?—J. D. E.

— Plants of this Carnation that have forced into bloom at an early period of the year often produce deformed blooms. For early blooming the plant should be layered in July, putting two strong layers in a 5-inch pot as soon as they are well rooted. By the end of the autumn the pots will be fairly filled with roots, and no more repotting will be necessary. It is when the plants are not well furnished with active roots, or are in too large pots, that imperfect blooms are produced. Too much moisture at the roots will have the same effect.—J. C. B.

FRUIT.

APPLE DUMELGOW'S SEEDLING (WELLINGTON).

The question of deterioration of this and other standard varieties need not give intending planters any uneasiness or prevent their being grown. Given an suitable soil and proper treatment, there is no fear of the ultimate result being anything but good. Near where I write there is an old orchard which contains fine old

Fruiting-branch of Apple "Dumelow's Seedling."

trees of *Ribston Pippin* that bear well and a large proportion of the fruits are large. These trees have holes at least 1 foot in diameter. In the same orchard are fine trees, quite as old, of the *Lemon Pippin*, *Dutch Codlin*, and the true old *Golden Pippin*. From these trees grafts were taken some two live or fifteen years ago, and the trees thus propagated now occupy another orchard, and are without exception in the finest health, forming a practical and conclusive reply to the deterioration theory. I quite believe that the pruning-knife has a great

deal to answer for, and that excessive pruning and the absurd system of double cropping (so called) have helped to produce canker and other evils. If fairly young trees, not too badly cankered, are allowed to have their heads, simply thinning the branches sufficiently to admit light and air and leaving them undisturbed at the roots, their improvement in their general health after a season or two will be marked. *Dumelow's Seedling* is never at its best unless allowed freedom of growth, with very little pruning more than keeping the centres of the trees clear from twigs and the main branches shapely. In common with the *Blenheim* and others, close pruning spoils all chance of a full crop. Two marked peculiarities of this Apple are the curiously speckled bark of the wood and the hammered appearance at the apex of the fruit. The tree, being a quick grower, should be allowed plenty of room to develop, a crowded orchard being especially bad for this kind. I fear that this Apple will not commend itself to those who prefer kinds which grow their own sugar, but there are others who think these latter insipid, and who prefer more piquantly acid fruit which requires artificial sweetening, and to those who think thus, one may say that *Dumelow's Seedling* or *Wellington* will beat all other late-keeping Apples for cooking. At the present time I have plenty of good *Norfolk Beauty*, but the colour when cooked is against this, so that it will not be asked for while the more attractive *Wellington* is to be had. A fruiting-branch of this fine Apple forms the subject of the annexed illustration. T.

FRUIT PROSPECTS.

NEVER in the recollection of the oldest gardener was there a better display of fruit blossom or finer weather to ensure a good set, and unless we get some very decided return of wintry weather the crop must be enormous. Of course, there are other causes of failure besides spring frosts, notably cold, cutting winds; but this year the icy chilliness we have usually experienced whenever the wind blew from north or east seems altogether absent, and the air has been quite mild, with just enough breeze to stir the pollen of the fruit blossoms, without doing any mischief. Pears and Plums have been completely covered with snowy blossoms, and *Chorice* also beautiful. Apples are fast expanding, and give promise of a marvellous display, the bloom being not only very abundant, but remarkably fine. Old and young trees are alike crowded with flowers, even maiden trees one year from bud or graft are blooming freely. The old fallacy about planting fruit trees for the next generation to get the benefit is getting pretty well exploded, as either the trees are getting more precocious in their bearing or else the mode of pruning favours early fruitfulness. Bush fruits are remarkably full of bloom, and *Gooseberries* are already formed and fast swelling up into fruits, so that at the present rate of progress we may look for good-sized fruits at *Whitsuntide*. Strawberries are pushing up fine sturdy flower spikes, and mulching the soil ought to be done at once, for drought is a great enemy to Strawberries and Raspberries, and in a fine season in light soils they need constant watchfulness to keep the roots from suffering. JAMES GROOM, Gosport.

3542.—Angle for a cool vinery.—An angle of 40 degs. will do very well for a cool vinery; but 45 degs. would do better, as in the latter case the action of the sun's rays is greater, which in the case of a cool vinery is an advantage. If, however, you wish to grow plants as well as Vines in the same house, the angle you mention will be best, as you will have more head room; but you will have to pay for the latter by the increased cost of the front wall or lights. I should mention that the steeper the roof of a vinery the more liable the foliage of the Vines is to get scorched, unless the structure is ventilated early in the morning.—J. C. C.

— Forty degs to 45 degs is a very good angle for a cool vinery.—E. H.

3520.—Black Humbergh Vine.—The Vine has been treated well, but owing to its being planted outside it has not made vigorous growth enough to produce fruit. After another year's growth it may be strong enough to do so. It would allow the following growth to run

up as far as they will go; the side-growths should be trained out, and stopped at the fifth leaf, and when the side-growths are stopped this will throw greater vigour into the leading shoots. When the Vines show fruit it is usual to stop the laterals at the first leaf beyond the bunch, stopping all other supplementary growths, and the Black Hamburg is the very best variety that would have been planted in the greenhouse.—J. D. E.

3554.—**Dying Peach branches.**—Dead branches should never be permitted to remain on Peach-trees. When these are cut out it is generally possible by rearranging the healthy branches to fill up the wall again with new growth. The probable cause of the presence of scale on Peach-trees is their weak state of health. The trees should have been washed when leafless and before the buds had started with Gishurst Compound, 4 oz. to the gallon of water. Blighted or blistered leaves should be pinched off.—E. H.

The Peach-tree seems to be in rather a sad plight, if there is an intention to wait until the entire side of the trees is dead before removing those that are dying. There is no reason why any branches should die upon a Peach-tree if the leaves were kept clean, and the roots in a healthy growing medium. Blight on the leaves and scale upon the wood will cause the young wood to decay, and after it is dead the sooner it is removed the better. The scale should be removed when the leaves fall in the autumn; wash them off with a brush and soft-soapy-water. Aphids on the leaves and mildew can both be destroyed by washing them with soft-soapy-water in which flowers of sulphur has been dissolved. The mixture can be applied with a syringe as soon as any of the parasites appear.—J. D. E.

3576.—**Vines in a coolhouse.**—The disbudding should be done as soon as the bunches are visible, leaving that showing the best bunch and removing the others. The tying down should begin before the shoots touch the glass. If the shoots are looped down as far as they bear without risking their splintering off they may be gone over a second time in weather like we have had lately in five or six days, and the final tying given in five days more. Stopping should be done as soon as the shoot extends beyond the second leaf. Two leaves are generally enough to leave. Some growers only leave one leaf beyond the bunch, but I like to have two, and should leave more if there is room without overcrowding.—E. H.

3570.—**Vine culture.**—The temperature of the house should not be kept too high, 55 degs. by night and 65 degs. by day will be ample until the Vines come into bloom, when both can be raised 5 degs. Admit air in the morning when the thermometer rises to 60 degs by opening the ventilators at the top a little, allowing the heat to rise along with air. Do not open the front lights, except for a short time during the middle of the day when the sun is shining brightly and wind from the east is not blowing at all. Much of the trouble from mildew in Vineries is caused by opening the front ventilators wide, thus causing a direct draught to blow over the bunches, chilling the air in the house. If the spurs are within 1 foot of each other on each side of the main rod the shoots should be disbudded to one at each spur. As a rule the bunches are visible on the new growth when this is a couple of inches long. Disbudding should take place immediately the best bunches can be seen. Pinch the point out of each side shoot two leaves beyond the bunch. Lateral growths will spring from the joints after the point is taken off. Remove these entirely below the bunch; above it allow one joint to be made first. Bend the shoots gradually down to the wires; if they are strong it will not be wise to pull them down more than an inch or so each day, or they may possibly snap off at the junction. Do not syringe the Vine at all after the bunches have formed, but moisten the paths, walls, and stages of the house twice daily, to create atmospheric moisture, which will to a great extent check the growth of red-spider, if the Vines are infested with this insidious pest. In the case, though, of wet or cold weather, the damping down process should cease for a time, to be again renewed upon a change to brighter weather. As the roots are in an outside border they may not require watering at all; so much,

however, depends upon circumstances regarding this. If the border is a raised one, unoccupied with any kind of plant and the roots near the surface, water may be required once or twice during the summer. It is, however, a good plan to mulch the surface with half-decayed horse-dung, about 3 inches thick. This prevents the moisture from evaporating from the soil so fast, keeps the surface cool, thus encouraging root action by preventing their being driven downwards in quest of moisture. The question of cropping the Vines is one of circumstances guided mainly by the health of the Vines and the weight of the individual bunches. A Vine covering 13 feet of rafter should carry 20 lb. of fruit. When the berries are the size of Peas, thinning should commence, nipping out the small berries, leaving room for those left to swell to their full size; without being unduly crowded.—S. P.

Thinning Peach and Nectarine flower-buds.—When buds on Peaches and Nectarines are few and well placed, I invariably find them set well and the fruit proportionately large. While shoots are allowed to remain crowded with buds large and small, the setting is less certain and the crowding of the flowers is against the strength of the fruit. When small and weak at first, they never attain the same perfection as selected buds, which have never been cramped for room by their fellows and had full liberty to expand on the best side of the shoots, fully exposed to sun and air. When shoots are heavily laden with buds, I run the finger up the backs of the shoots, clearing off every bud, and then the front buds are thinned a little later, so that they can be allowed all the space the fully-developed flowers require. A deal of bud-thinning can be done in a few hours. I think it was from reading Mr. Coleman's notes on Peach management that I was induced to strip the buds from the backs of the shoots in the summary manner indicated. I have thinned Peach buds always when they required it for more than a quarter of a century, and experiments frequently practised have taught me that the small amount of labour expended is highly beneficial. On our early trees this year I have had to thin off thousands of fruit after bud-thinning was practised. Some trees were left unthinned. Though heavily cropped, they have not the display of large, well-placed fruits. Thinning of wood buds is generally done as soon as they can be picked out—before the fruit buds are much on the move. One shoot is left at the base of its predecessor to supply fruit next season, and a shoot is left as a leader at the top of the fruit-bearing one to lead up nourishment.—M.

Moisture for Apricots.—During May it is certainly advisable to give Apricots plenty of moisture and nourishment if the soil is light or porous, as it is surprising the amount of water and feeding stone fruits will take when in poor light soils. I have of late lifted my Apricot-trees every third or fourth year and given new feeding material—good loam, not rank manure. No matter how old, all have been treated in this way, and some large old trees of *ifemerkirk* have been removed to different positions with excellent results, as they bear large quantities of fruit and do not canker as formerly. Apricots delight in a compost with which mortar-rubble, charcoal refuse, brick rubbish, and burnt earth are largely incorporated. This material requires a lot of moisture, and as the bottom of the border is thoroughly drained, it seems as if the roots revel in unlimited supplies of moisture and feeding. As our trees are on raised borders we feed well, often giving liquid manure and mulching at this season. I find the nearer the roots of the Apricot can be kept to the surface the better, and if these are healthy there is little canker. The periodical lifting encourages this surface-rooting. The lifting is done in September before the trees shed their foliage. The roots of large trees are cut round one autumn and lifting is done the next.—H.

3557.—**Sewage water.**—House sewage may be profitably used for all strong-growing plants and fruit-bushes when diluted, but should not be given to any delicate plant, and it is not adapted for plants in pots in the greenhouse.—E. H.

"H. C." is quite right. Sewage water properly diluted is invaluable for the garden. I have used hundreds of gallons of it during the

past month, both for plants in pots in the greenhouse and for Apricots and other established trees in the open, and if I had sufficient I should apply it to Peas, Cauliflowers, and similar vegetable crops, also to Raspberries and Gooseberry and Currant-bushes. My Strawberries want root-melature very badly; but in my strong soil the liquid sewage causes them to run too much to leaf. In lighter ground it would benefit the crop immensely.—J. C. C.

ORCHIDS.

CYPRIPEDIUM PHILIPPENSE.

I HAVE received a flower of this plant from "J. Edmonds," asking if it is *C. Sandermanii*, and he also wishes for a few words as to its treatment? This *Cypridium* was sent home here in the first place by Mr. John Veitch when engaged in collecting Orchids for his father, about thirty years ago, or nearly so, and it was named upon its first flowering *C. levigatum*. I think it was Bateman who thus named it, but it was afterwards found to have been named before from dried specimens by Reichenbach as *C. philippense*. At first it was very rare, and it commanded long prices, and for some time this plant appeared difficult to manage, and so it remains to this day if it does not get just what it requires. Mr. Sander, of St. Albans, introduced some five years ago a very similar plant, which he called *C. Roebelinii* after the collector that sent it him, and which many people now assert to be the same plant as *C. levigatum*, but I really do think there is a varietal difference. It belongs to the same section as *C. Sandermanii*, and so does *C. Parishii*, *C. Ruthechildianum*, and one or two others that we know; but your flower appears to me to be the true form of the plant sent home by Mr. J. Veitch. This Orchid comes from one of the hottest parts of the world, and it grows naturally exposed to the full heat of the sun at nearly the level of the sea, so you may imagine it requires much heat under cultivation. I have found this plant and all the others belonging to this section thrive best in a house in which the temperature does not fall lower than about 65 degs. at any time in the year, and in the summer, of course, it will be much hotter. This and all others of the section may be potted in a similar manner to the majority of the *Cypridiums*, draining the pots exceptionally well, and as before said, keeping them in the warmest house, and also maintaining a very moist atmosphere, and well exposing the plants to the light. I know of no other matter which will tend to their welfare, saving in not overloading their roots with the soil, and the leaves should also be frequently wiped with the sponge to keep away that direful enemy, the black thrips, and in doing this take the greatest care not to break the leaves, or the remedy will be as bad as the disease. MATT BRAMBLE.

A new hardy plant.—A very pretty hardy plant, introduced in 1891 from Japan by Capt. Torrens, Baston Manor, Hayes, Kent, is called *Schizocodon soldanelloides*. It is allied to the beautiful *Shortia galacifolia*, and is a plant that one would think amateurs would take to. It has been known many years, but never brought to England alive until 1891. It does not seem difficult to grow and flowers very freely, the leaves not very large, and the flower-stems are short, the flowers about as large as a farthing, prettily fringed, and of a pink colour. It makes a mass of colour with its many bright rosy-pink blooms. I do not know whether it is hardy, but it seems to like the same kind of treatment as *Shortia galacifolia*—i.e., a fairly moist soil, and will succeed well in pots. It is named *soldanelloides* from the aspect of the flowers being like that of a *Soldanella*.—C. T.

THE KITCHEN GARDEN.

OPEN-AIR TOMATOES.

In the cultivation of Tomatoes in the open air there are two extremes to guard against—viz, the starvation treatment on the one hand, and overfeeding on the other. In inverted plants stems and leaves are certainly large, but so devoid of stamina as to easily fall a prey to disease, while the fruits do not set freely. The soil the plants are being prepared in must not be overrich upon any account, neither must the stations nor borders for planting. These latter are very often too loose and rich; consequently the plants ramble away and make a soft, immature growth. Some of the best crops of Tomatoes I have ever seen were produced from plants growing in large pots and boxes, half plunged, against a sunny south wall. This system can be strongly recommended, but there must be no lack of attention in watering and feeding, especially if a dry time should ensue. I have seen plants even when growing in this open up against south walls, where the root room

be kept growing in a fairly warm and airy structure, and be repotted into 7-inch pots as they become ready. Any neglect in potting on the plants is prejudicial to them. Exposing the plants or hardening them off too early preparatory to planting out is a poor method to adopt. The middle of May may be quite time enough to commence inuring the plants to cooler treatment by removing them to an airy pit, and by the end of the month the plants may be fully exposed, during the daytime at any rate. After this date it will depend upon the season whether they may be set out or not, but about the first week in June, or even a week later, there need be but little fear in trusting them in the open, as after planting a slight protection may be afforded for a few nights. I am much in favour of confining the plants to single stems, although I see no good reason why two, or even three, stems should not be encouraged from each plant, the main point being to keep all lateral shoots rubbed out as soon as perceived. I have certainly seen and also grown good plants fan-shaped; but it depends largely upon the season whether this form may be encouraged. During

yet invented gives the same practical results. With one exception, I think the tall-growing Peas are preferable to dwarf ones; the exception is in the case of the first early, and this is owing to the fact that in all Peas I place individual quality of the Peas in front of mere quantity. Peas are grown for flavour and not for the number borne in each pod. For a first early I prefer Cannell's English Wonder, a variety growing not more than 18 inches high. William I. may give a greater quantity of pods, but the quality of the Peas is but second rate. As main-crop sorts I prefer Duke of Albany, Duchess, and Fortyfold. The last named is not an exhibition Pea, as things go nowadays; but for supplying the table with Peas of exquisite flavour this Pea cannot be surpassed. In height it grows 6 feet in well-managed soil. The latest crop is produced by No Plus Ultra; short in the pod it may be, but good in flavour, and plentifully borne. More than this, as a mildew-resisting variety this is quite the best. Where tall stakes are a hindrance Vastor's Perfection and Stratagem are good substitutes; neither of

Tomatoes in the open air at Burleigh.

was not restricted, suffer to such an extent from the want of moisture at the roots as to cause the foliage to curl up and have a decided bluish cast. Narrow borders raised above the surface can be highly recommended, as by this method the roots are in a warmer medium, and, being partially confined, they do not ramble away, but make a firm and fruitful growth. A stout plank placed on edge about 18 inches from the wall will be sufficient space, but it must be remembered that, the root-run being curtailed, feeding and watering must not be neglected. Again,

THE SOIL provided for the plants to root in is often too rich. Some fertile loam or even ordinary soil, with a fifth of pulverised horse-manure rubbed through a sieve, with a fair proportion of wood-ashes, will form a root-run capable of supporting the plants until the fruit is well advanced. If I knew that the soil was not of a fertile nature, a little superphosphate and kainit as a source for potash would be added, and with the certainty of the plants making a satisfactory growth. We must first promote a firm growth, then feed after the plants need support, this being according to the nature of the season, soil, and extent of root-run. The plants from the earliest stage must

a favourable time it is very easy to allow a few lateral shoots to form, so as to extend the growth of the plants if needed, these being topped after a bunch or two of fruit has set. Tomatoes are essentially sun-loving plants, and they must be so grown that almost every gleam of sunshine can reach them. A good example of open ground Tomato culture is shown in the annexed illustration. A.

NOTES ON PEA CULTURE.

PERHAPS there is no other vegetable that is looked upon so favourably, apart from the Potato, as a well-developed Pea. It may be that this crop is regarded as a luxury, but it is one that gives an excellent return for labour expended. As in all matters affecting the amateur as to vegetable crops, the question of a selection of suitable varieties is the most important. Without good sorts successful results cannot be expected in the same sense as where none but those are cultivated. Tall-growing varieties are, it is well known, more productive of a crop than dwarf sorts. The reasons are obvious. The point of objection lies in the difficulty of providing stakes sufficiently tall for varieties over 3 feet high. Unfortunately, no substitute

these grow beyond 3 feet high. The Pea is one of the few vegetables that do not absorb nitrogen from the soil; therefore, to apply this chemical in the form of nitrate of soda is simply a waste. The haulm may be slightly increased in length, but the quantity of the pods is none the more.

MANURE is essential to success, but it should not be applied in the manner that some suggest—viz., digging out a trench as if for Celery, placing a thick layer at the bottom, covering it with soil, and sowing the seed thereon. The objection to this plan of cultivation is that the roots quickly find their way through the manure to the sides of the trench, which they cannot penetrate, owing to the manner in which the latter was cut out of the solid ground. The roots in this limited area of this trench quickly absorb the moisture from the manure, and in the case of a few dry days the plants are languish for more, hence mildew quickly takes possession of the haulm, and failure rapidly follows. It is much better to deeply dig the ground over in the autumn, adding manure freely then, and when sowing the seed draw out a wide drill with a hoe, allowing at least 3 inches between each Pea. In land deeply dug the roots have an opportunity of rambling away at will,

and are less liable to drought, and, consequently, are more secure from mildew. So many amateur cultivators spoil their chances of success by sowing the seed too thick; they seem to think that the thicker the Peas are laid the greater number of pods will be borne. Peas object to be overcrowded perhaps more than any other vegetable. Weak haulm means a correspondingly thin crop of pods. Space for a free development of the leaves and haulm induces also a trenching habit, which is favourable to a full crop.

MULCHING the surface soil for at least 18 inches away from the row on each side, conserves the moisture in the soil, and by the aid of frequent waterings the manurial property is washed down to the roots, which thus receive the benefit from the manure in two ways. Moisture at the roots is essential to success during dry weather. The time in watering Peas is well spent. Where mulching is practised it is doubly so. Another mistake most common is that of neglect in staking the Peas. Support directly to the tendrils are visible on the plants is absolutely necessary to success. To permit the plants to grow 1 foot high before tendering them any support, and allowing the haulm to fall on one side, thus crippling its progress at this early stage, is a practice strongly to be condemned, but, I am sorry to say, it is very common. I am not in favour of the practice of topping the points of the plants at a certain height to induce a greater crop of Peas to form by concentrating the energy of the plant into a limited number of pods, except in the case of requiring them for some special purpose, such as exhibition. I favour an extended growth up to 8 feet if the plants seem inclined to grow that much.

S. P.

3563—Manure for Potatoes.—Superphosphate of lime is an excellent fertiliser for Potatoes under any circumstances, and probably the best thing, generally speaking, that could be employed. It should be sprinkled in the drills when planting at the rate of 4 cwt. or 5 cwt. to the acre. It is also useful for Onions and other root crops, and I fancy does Peas and Beans some amount of good, but for all such it ought to be worked into the ground a few inches, and not be allowed to come in contact with the seeds. Keinit is beneficial to Potatoes on light or hungry land, but is of no use on a damp or heavy staple, or where much farmyard manure is used.—B. C. R.

3574—Forcing Seakale.—Seakale may either be forced where grown, covered with pots, which should be surrounded with warm manure mixed with tree-leaves, or the roots may be lifted when the foliage dies off, and forced in any warm place where the light is excluded. Seakale may be forced in deep boxes with close fitting lids in a warm greenhouse in any dark corner under the stage, or they may be planted 3 inches or 4 inches apart in a genial hot-bed, the frame to be closely matted up. I have used frames for this purpose fitted with wooden shutters instead of glazed lights. A bed suitable for forcing Potatoes will produce good Seakale.—E. H.

3568.—Tomatoes in a small house.—Tomatoes drop their blooms from various causes, but in this instance I incline to attribute it to an overmoist and close atmosphere, especially at night. Until the plants have a pound or two of fruit set on each it is best to keep them rather on the dry side, but when well laden water and liquid-manure may be given freely, yet not till the soil becomes moderately dry. Again, with a night temperature of 55 degs. a little air ought to be left on at the roof at night as well as by day, unless it is very stormy outside. My idea is that with so much moisture, and a high night temperature with no air on, the atmosphere becomes too humid, and this causes the blooms to drop. You can scarcely ventilate Tomatoes too freely, as long as the temperature of the house does not fall below 50 degs. Of course the plants are not shaded in any way.—B. C. R.

— Yours is a very common trouble early in the season. The cause of the flowers dropping is because the fruit did not set. The season will set this matter right as it advances; meanwhile keep the air of the house warm and dry. Maintain the same night temperature, and when the weather is fairly mild, give a little air.

at the top of the house all night. The flowers also drop off sometimes later in the season after some fruit is set, which I believe to be caused by the inability of the plants to sustain them. It has often been suggested that the flowers should be fertilised to help them to set their fruit, but I get as good crops and quite as early since I have left off doing so as I did before. As a matter of fact, I have dissected many of the flowers, and although all the parts that go to make up a perfect flower may be present, they are so placed that I cannot see how the cultivator is to manipulate upon them in a way that will assist fertilisation.—J. C. C.

3579.—Cucumber plants dying.—You have put your question so clearly that I cannot think there is much doubt about what is the cause of the plants dying off so mysteriously, as it is clearly traceable to the soil, which either engenders canker in the stem, or else it is infested with some insect that penetrates the roots of the plants, which causes them to suddenly collapse. It is one of those cases that require minute inspection of the dead plants before one could say whether the injury is caused by canker or insects. I may tell you that your arrangement of the bed of soil on a bench over hot-water pipes is just such a one where the plants would suffer for the want of root moisture; but the intelligent way in which you have stated your case does not point to that direction as the cause of the injury. I advise you to keep up a relay of fresh plants to make good any failures that occur this season, and next year to start with fresh soil obtained from a distance.—J. C. C.

3558.—Seakale from seeds.—Seakale-roots may be raised from seeds, though it is rather late for sowing now. The young plants ought to be coming up now. Sow in drills 1 inch deep and 15 inches apart. Thin the plants to 1 foot. To grow strong roots in one season requires good land and cleanly culture. Seeds sown now may produce roots for planting out next March; but they will not be strong enough for forcing. Cuttings of the roots make the best plants. The cuttings are usually taken off the roots when lifted for forcing, are laid in moist earth or sand till March, and are then planted out. The root cuttings should be about 4 inches or 5 inches long. The old roots now in boxes should be taken out and cut up and planted. They will probably make roots strong enough for forcing in boxes next winter if well cared for.—E. H.

— I raise a large number of plants from seed annually. Sow in March in drills drawn the same depth as for Peas. Sow or plant the seeds about 3 inches asunder in rows about 14 inches apart. They will grow into good-sized plants by the end of the season, but they require another season's growth before they are large enough to force. I have used a few of the larger one-year-old plants for forcing sometimes, but the heads are not the full size. The roots that have been grown in deep boxes outside may be again grown to force another year; after the heads of Kale have been cut for use, a number of shoots will start from the crowns underneath the cut part, but they ought all to be removed except the strongest one.—J. D. E.

3549.—"Pipy" Celery.—Checks of any kind will make Celery "pipy." Rank manure with the roots thrust into it is a likely cause, especially as you say you plant deep. The manure for Celery should be well decomposed, and should be forked into the bottom of the trench, and well blended with the soil. But there should always be soil enough for the manure for the Celery to be planted in without coming into contact with the manure immediately. I think sinking the bell of roots into rank manure when first planted often leads to pipy Celery and holting.—E. H.

— There is more than one cause why Celery becomes "pipy"; but more frequently than not it is through sowing the seed too early and growing on the plants in too high a temperature. For a main-crop the beginning of March is soon enough to sow the seed for the North of England, and an ordinary greenhouse warm enough to bring on the plants, and a month later does admirably for other parts. Liquid stimulants will also cause the mischief. Use a moderate quantity of rotten manure in the trenches, and give plenty of clear water in dry weather, and do not commence forcing too early.—J. C. C.

EARLY RUNNER BEANS.

THERE is much difference in this vegetable. Some people prefer the white kinds (that is, those varieties that have white blossoms) to those with scarlet flowers. For early use I prefer them, and I may be wrong, but I fancy their pods are more succulent than those of the scarlet form and other kinds in cultivation. I have grown the Giant White, and it is one of the best. Last season this variety yielded enormously, bearing very large, thick, fleshy pods of great length and of excellent quality. I had previously grown the large white, but this variety is far superior and of equal quality. I think this variety must be a selection from The Czar, as it resembles that variety in shape, but is, I consider, of better flavour. There is also another runner with white seed named Mammoth White and very much like Giant White. For exhibition the above varieties are excellent. To obtain early runner Beans is worth a little trouble, and they can be readily raised indoors by sowing in the middle or third week of April in pots or boxes in frames, and when up giving thorough exposure to get properly hardened for planting. When this plan is adopted, the runners give a lot of Beans some time in advance of those sown in the open ground. I do not mean that the scarlet-flowered varieties do not succeed as well as the white-flowered, but having tried them both together, I find the white-flowered varieties a few days in advance of the scarlet type. I know there are often failures with these Beans when sown in heat and planted out. This is owing to a variety of circumstances; many succumb to cold winds, having been improperly hardened, as Beans are extremely tender, and if sown in heat require careful management before exposing to all weathers; indeed, I think there is little gain by sowing in heat either these or the dwarf French varieties, and I prefer cold frames. If sown in 4½-inch pots in April in

A COLD FRAME, giving no water till the seed has germinated, and growing as close to the glass as possible, sturdy plants result by the second week in May, when they can be planted out in a light soil. If the ground is very heavy or of a clayey nature, it is best to prepare a suitable piece by freely using light soil for the drills. It is best for these early Beans to prepare a trench similar to that for Celery, placing the light compost on the surface in the trench for planting the Beans. When a trench is used, the Beans are sheltered from cold winds and readily protected at night by laying a few sticks across the trench to support mats or shading material, and in dry weather are more readily supplied with moisture. These Beans may be grown without any stakes. Of course, they do not yield like those staked, but for early use the pinching necessary to keep them dwarf throws them into bearing earlier, and this is important when they are required for early use. When grown dwarf, pinching the tops should take place when they have reached 18 inches to 2 feet high, and they should be planted much closer together—3 feet to 5 feet is ample. Very often in light soils, with a deficiency of moisture, the flowers drop prematurely, owing to drought, but with dwarf kinds this rarely occurs, and it is easily prevented by placing litter between the rows. Some may object to growing Runners in this way, and advise sowing the dwarf French Beans, which are most serviceable for the earlier supplies, but for summer use soon become tough and stringy, and do not continue to yield like the Runner, which will give supplies till out down by frost. I also advise the culture of the Butter Bean. This forms a pleasing novelty, is of superior quality when cooked whole, and is not tough if gathered young. G.

3323.—Treatment of Palms, &c., in jardiniere.—If these plants are growing without drainage in China bowls their roots are probably so much destroyed as to be practically useless, and for this reason it is impossible for them to thrive. The roots of all growing plants require a certain amount of air, such as can be had through porous earthenware, and also they need to get rid of standing water, which soon becomes sour and rots them. The only exception to this rule is in the case of some aquatic plants. For drawing-room decoration, plants such as Palms, Aspidistras, Ferns, &c.,

must be placed in clean pots, with excellent drainage, arranged so as to allow the free egress of water, and covered with a bit of Moss to keep the drainage from being choked with soil, which otherwise is apt to silt down into the chinks and close them. If the plants are not too far gone they had better be placed at once in pots only large enough to hold them comfortably, which can be slipped into jardinières when necessary, with a compost of two parts peat to one of loam packed firmly round them. They should then be put into a warm conservatory or hot-house, when they may, after some months, throw out fresh fronds and leaves, and in time recover their health; but if they have become shabby and the roots are in a bad way, it would be wiser to throw them away and start with fresh plants, for they will never be good for much.—
I. L. R.

GARDEN ENTRANCES.

IN reply to "G. B.," "R. H.," and others on this matter, we call attention to the annexed engraving, which faithfully portrays the entrance to the kitchen and fruit garden at Heckfield Place, Hants, during the late head-gardener's (Mr. Wildsmith's) lifetime, and is, in fact,

their parentage in part to *R. ciliatum* there is not one whose value in the greenhouse surpasses this. A specimen over 3 feet in diameter planted out in one of the beds in the large temperate-house at Kew is generally about now in its greatest beauty, the trusses of bloom being unusually large for this class of *Rhododendrons*. Owing to its rapid growth, this hybrid is of somewhat loose, but elegant habit, and to keep it in shape the longer shoots should be cut back several inches each season after flowering. It is at the same time a dwarf plant, and will probably attain no greater height than *R. ciliatum*, which is rarely more than 2 feet high. The leaves are about 3 inches long, pointed, and covered with fine short hairs. The flowers are borne in rounded trusses each from 4 inches to 6 inches in diameter, and pure white. The free-flowering qualities which are well known to be characteristic of this section of *Rhododendron* are in no instance more apparent than in this representative. Cuttings strike freely if placed in very fine sandy peat and kept close in a moderately warm case. Their growth is somewhat impeded in a young state on account of their forming a flower-bud on every branch, even when only an inch or

sized clump being placed in a pot that will admit of three-quarters of an inch of soil being placed between the roots and the sides of the pots. The pots can be stood away in any cool place free from frost, or they can be stood in the open and treated as bulbs are for forcing into bloom, by being covered with leaves and manure. When they begin to grow, all the light possible should fall upon them, and air be given on all convenient occasions to keep the plants sturdy. There should be no lack of water, and if the plants could be stood in the open and have the benefit of a warm spring shower, they would be all the better for it. The roots so adapt themselves to division that a stock can soon be worked up. A large number of roots of this perennial are annually imported from Holland.
R.

DAFFODILS FOR POT CULTURE.

I THINK it must be admitted that very little use is made of the genus *Narcissus* as compared with other groups of spring flowers, as, for example, *Hyacinths*, *Tulips*, and such like, bulbs which undoubtedly make a rich and effective display in the conservatory or greenhouse. To my mind, both these bulbs lack in a great measure the general elegance and beauty which characterize many *Daffodils*. As cut flowers, from a commercial point of view, these *Daffodils* hold a good position, or at least many of them, but as pot plants they have yet to become popular. It would, I think, materially assist to this end if the leading growers of these flowers were to make special efforts in this direction, and so let the public see that *Daffodils* are specially adapted for pot culture. True it is, we have them in endless numbers as cut flowers in the spring months, and a few occasionally in pots here and there, but nothing approaching a representative display. By reason of the present mode of arranging cut flowers of these things for exhibition, much, if not all, of their natural grace and beauty is lost. There is such a number of forms and colours, that one wonders why they are not in more general use, even if only for the sake of variety. And then, again, the majority are so readily grown in English gardens, that by exercising due care when flowering is completed, and planting them out in good ground, one may soon be possessed of a nice stock for future use. Some kinds—indeed, many—are suited to forcing earlier in the year, but I am not at the present moment referring to this so much as to endeavour to secure a more general use for these *Daffodils* as pot plants, blooming, it may be, a few weeks in advance of those in the open ground, and thereby prolonging the flowering season. Nor is this all, for it is impossible to overestimate the superiority of those flowers which are grown under glass to that of those expanding or partially so in the open ground. Dwellers near large towns know well enough that every shower of rain brings with it its quota of smut and soot, and this once upon the flower robs them of much of their purity, and defies all attempts to cleanse them afterwards. But grown under glass, even in a cold-house, all their purity may be preserved, and the flowers may be inspected at will and seen to the best possible advantage. In this way many amateurs with cold-houses could not possibly have them better occupied in the early months of the year. By flowering them, too, very near to their natural season, there would be no great strain upon the bulbs, which may be left to bloom another year in the same pots, or shifted into larger ones, as the case demands. Few kinds can display themselves to greater advantage when given this

COOL TREATMENT under glass than that noble bicolor, *Empress*. In the open ground it is, of course, a grand flower too, but the protection I have named brings out all its purity and gives it a refinement that can never be seen in the open ground. The flowers, too, are very lasting, even when fully expanded, particularly so if overhead watering be carefully avoided. The variety *Horsfieldi* is also beautiful, not so bold generally, but somewhat earlier, while a later variety may be found in *Gravées*. Three bulbs of either of these would be sufficient for an 8 inch pot, shifting into a larger size as necessary. The variety *princeps* is useful when grown in this way, and though its segments are somewhat thin and thin, it possesses a grace of its own and, indeed, is preferred by

Garden entrance at Heckfield Place, Hants.

a view of central walk leading on to the pleasure grounds. Throughout the entire length of walk there are flower borders on each side, some 4 feet in width, backed by hedges of Lawson's Cypress. The borders, as far as the first arch, are wholly planted with herbaceous perennials, and the trellis work over the walk is covered with Clematises, Roses, and Honeysuckles. Beyond the first arch are borders of much greater length, which in winter are furnished with small shrubs of various kinds, mainly Japanese *Retinosporas*, and in summer with flowers somewhat after the bedding-out form, only by mixture of plants, in preference to masses of one kind. Single and Cactus Dahlias, *Gladiolus*, *Hyacinthus candicans*, *Herbaceous Lobelias*, *Marguerites*, *Marvels of Peru*, and large *Pelargoniums* occupy the space next to the Cypress hedge, the front part of borders being filled with dwarfier plants of various kinds, such as *Heriaria*, *Sedum*, *Antennaria*, and the like. We do not know a better or more effective way of laying out and planting the borders, &c., than is here given, and we recommend our querists and others to follow it out as far as their space, &c., will allow.

two high; these should, therefore, be removed as soon as formed until the plant reaches a suitable size to develop them.

DIELYTRA SPECTABILIS.

THIS *Dielytra* is very useful in many ways. It is one of our best forcing plants, and large clumps of it grown in pots or tubs are most useful for conservatories, while smaller specimens are valuable in the greenhouse for mixing with *Azaleas*, *Epacris*, *Narcissi*, and many others. It is equally valuable in the open border; it will grow almost anywhere and in any soil, and with a freedom that is most grateful. Then the roots can be divided, and if planted out in nursery-beds, soon grow into large established clumps of a serviceable character. I think the best time to divide is when the foliage begins to turn a little yellow in early autumn. When I divide, I dig out a trench, put into it some refuse soil from the potting-bench, and cover the roots with it, treading the soil firmly about them, and if the weather is dry, a good soaking of water is given after three or four days. *Dielytra spectabilis* requires a great deal of moisture, and occasionally it seems like a pail or two of soap-suds, especially so when the sun is hot. It makes a good window plant, and can be potted in September and October, a good

Rhododendron multiflorum. Of all the numerous hybrid *Rhododendrons* which owe

some for this very reason. It is by no means a formal flower. There is one group to which I wish particularly to direct attention, and which for some reason or other is by no means popular for cutting. This is the Leedal group, probably the more chaste of all, and singularly beautiful when grown in pots for home decoration. When fully expanded, the flowers, unfortunately, do not travel well, and this may to some extent account for their not selling in the market. This fact need not exclude them from being grown as pot plants for home decoration. Very beautiful are the starchy blossoms of the type, and being sufficiently pure, I have repeatedly used flowers of this in memorial wreaths or the like. This kind should be planted more thickly together, say six bulbs for a 7-inch pot. The variety Stella is a light, graceful flower, and there are endless others among the single incomparabilis section equally well suited, and all more or less beautiful. Among the golden trumpet kinds, Golden Spar and maximus are excellent. Sir Watkin and Emperor are both first-rate kinds and very telling, possessing excellent constitutions and multiplying freely, points that must not be overlooked. But apart from all these there are the kinds usually forced in quantity, such as ornatus, obvallaris, and others, and, of course, equally well adapted to the purpose here indicated. I am not much in favour of the double kinds for pot work, for they must be staked, and in the case of the remainder I find it best to plant them as deeply as possible in the pots, as this gives better support for the leaves and stems than when the bulbs are only just buried. The variety ornatus is very liable to fall about if not just covered with soil, but if buried 3 inches deep in 8-inch pots, they stand much more firmly and a very slight support is sufficient. It is the best of this section, and being cheap, may be grown in large quantities. Quite a small bulb of this variety produces a good flower, and a dozen flowering roots may readily be accommodated in an 8-inch pot. E.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *Gardening Illustrated* if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *Gardening Illustrated*, 57, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *Gardening Illustrated* has to send press notes in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *Gardening Illustrated* should mention the number in which they appeared.

3602.—Wireworms and bulbs.—What is the best remedy for destroying wireworms without injuring bulbs?—GREENWICK.

3603.—Forcing Rhubarb for market.—Would anyone kindly give me all particulars how to force Rhubarb for the early market?—M. B. J.

3604.—Erics after flowering.—Will anyone kindly give me directions regarding the treatment of Erics after they have blossomed in pots?—BELLFIELD.

3605.—Deutzias in pots.—Should Deutzias (flowered in pots) be cut down when out of flower, and what is the general treatment for summer?—J. WOODWARD, Stamford.

3606.—Hydrangeas for market.—Would someone please give me the names of the best Hydrangeas for market, and state how they are best propagated and grown?—M. S. J.

3607.—Treatment of Palms.—Will anyone kindly give me some information concerning Palms, and state whether they require large pots, time for potting, nature of manure, &c.?—JANU.

3608.—Double Cineraria becoming single.—Would someone kindly state what makes my double Cineraria bear single flowers this year? Last season it bore nice double blossoms.—B. E.

3609.—Watering a garden.—I shall feel much obliged if someone will kindly tell me if it would injure my garden to water it during this dry and sunny weather, with cold winds and sometimes frost at night, as my gardener tells me it would do more harm than good to apply water?—EWE.

3610.—Training Peaches.—Can Peaches on a garden wall be advantageously trained on standard wall spallier wire or wire-netting, or is there anything better and easier than nailing to the wall?—T. G.

3611.—Vines the first year.—How and when to step the side-shoots? How far apart should these be? The side-shoots are about of an oval length up the rods, and with flower-bunches showing on each.—T. G.

3612.—Lime-water and worms.—Is the lime-water used to get worms out of flower-pots the clear water after lime has settled, and may it be safely used with all plants; or is there anything preferable?—T. G.

3613.—Flowers for a wall.—Will someone kindly tell me what flowers I may grow on an east-north-east wall? There is a border under the wall. Would *Pansies*, *Sweet Sultan*, *Candytuft*, *Centurion Bellis*, &c., grow in such a situation?—ARMINA.

3614.—Dark spots on Tomato-leaves.—How can I prevent dark spots coming on the leaves? It appears to be a kind of fungus. The plants are growing in pots in a greenhouse entirely to themselves, full south, light and airy; no heat but the sun.—O. C. S.

3615.—Flower-pots.—Ordinary flower-pots are not very ornamental. I should feel much obliged if somebody would inform me where I can obtain pots answering the same purpose, but more ornamental and suitable to be placed on the dining-room table.—H.

3616.—Cacti from seeds.—I have some *Cacti* just come through, they are like little round bulbs about the size of a Pea, they are in a notch in the top and a few little white bristles in between the notch. Is that the way they grow, or are they no good?—B. E.

3617.—Canna seed not growing.—Will someone kindly tell me why some seeds of *Canna indica* superba, planted in pots in a greenhouse, with a temperature of 55 degs., sown two months ago, have not yet shown the least signs of germination and what I should do?—W. B.

3618.—Treatment of a Myrtle.—I have a Myrtle, but I am anxious it should bloom. My treatment, I fear, is wrong. Will "J. C. G." or someone else, kindly give me a hint as to treatment? It is a fine healthy bush, and is kept in a greenhouse, but it will not flower.—J. B.

3619.—Culture of Gloxinias.—Will someone kindly give a few hints on the culture of my Gloxinias; they are now changing leaf, and when will they be likely to bloom? I have read that they flower in six months from the time of sowing the seed. Is this so?—B. E.

3620.—Anemones at Nice, &c.—Will anyone please tell me the names of the lovely double pale Pink Anemones that grow so splendidly at Nice, Cannes, and Menton, and also the names of the Double Scarlet? I also wish to know if it is now too late to plant any of them?—EMM.

3621.—Willows from seed.—Will someone kindly tell me how to raise the common Willow from seed? I know the usual way from cuttings, but I want to get some from seed, and I should like to know when they should be collected and how treated afterwards?—EAST KENT.

3622.—Tuberoses in a hot-bed.—I have Tuberoses in a hot-bed, it has thrown up two shoots from the crown and seven or eight round the base of the bulb. Shall I take them off and leave the two on the crown; and if I pot them will they root and flower or shall I throw them away?—B. E.

3623.—Superphosphate and nitrate of soda.—I have about 1 cwt. each of superphosphate and nitrate of soda and shall be glad to know in what quantities I should now apply it to the surface soil of garden Apple, Pear, and Plum-trees, also if dry and watered in, or dissolved in water?—CORDON.

3624.—Bulbs from Capetown.—I have just received from Capetown bulbs of the following: *Amesylepis*, *Belladonna*, *Watsonia marginata*, *Lilia maculata*, *L. viridiflora*, *L. stratioides*, *Freesia africana*, *alba*, *Babiana macrantha*. Will someone please to inform me which of them will do planted in the open air?—M. K.

3625.—Hyacinths and Tulips.—I had two boxes made 4 feet long, 3 feet wide, and 2 feet deep, with holes at bottom and sides, 4 loches of clinkers at bottom, the rest potting mould. They have done very well. I should like to keep them in the boxes without moving them. Would "J. C. G." tell me whether they will succeed that way?—W. D.

3626.—Strawberry flowers.—I am anxious to know whether you can account for Strawberry blooms opening with black hearts? Does it arise from frost or disease, and can anything be done to prevent it. Last year I thought it arose from frost at the time when the blooms were opening, but at present there is great heat, and my gardener is very much puzzled so to be the cause of it.—MRS. MELVILLE.

3627.—Cyclamen culture.—Would someone kindly give me a few hints on Cyclamen culture? My friend has some plants which do not do very well, the bloom is poor and the leaves do not come very large; they are stood out in the summer till time to take them in, and are kept pretty dry and potted at the proper time, and then they do not do well. Would broken manure mixed with the soil or bone-meal be of any good?—B. E.

3628.—Auriculas in pots.—Two years ago I struck some offsets of Auriculas in small pots, and last spring I had very good blooms. I then repotted the plants entire, and this year the blooms are weak and unsatisfactory. I suppose all offsets should have been taken off and struck, repotting old plants in small pots. Is this the case? In order to save trouble and produce a better show, would it answer to place several offsets together (but rooted separately) in a 5-inch pot? What compost should be used? How should varieties which are shy of producing offsets be treated in order to induce them to do so freely?—O. B. W.

3629.—Creepers for a trellis.—I shall be glad if anyone will give me a hint as to some pretty creepers, other than ivy, which would do to cover a trellis at the east end of my small garden? The sun is quite shut out at the east end by trees (Limes), backed by a very lofty building. The sun never touches the part of the wall I wish to cover till it reaches south-south-west at the present time, and in the winter scarcely at all. If anyone

can suggest any creeper of such an enterprising character to be likely to succeed in such an unpromising position, I shall be very grateful if they will let me know what it is? The soil is, of course, impoverished by the roots of the Lime-trees.—CALCUTTA.

3630.—Loam for Chrysanthemums.—Is it best to sift fibrous loam after it has been well pulled to pieces through an loach sieve for potting Chrysanthemums? Is putting the rough fibre over the crooks right; or is it best to leave all the fibre in the soil? I see "E. M." in *Gardening Illustrated*, April 15th, says that it ought to be used in a rough state; but, not having used any before till this season, I did not know if there would be any harm in leaving all the fibre in, as there seemed such a lot of it without sifting it. And would "E. M." tell me where I can get blue loam on Chrysanthemums and the price? I shall be much obliged for advice.—W. D.

3631.—Climbing Roses for a house wall.—Will someone be good enough to give me the names of two or three climbing Roses of different colours suitable for planting against a house wall with a north-east aspect (on which there is little sun except in quite the early morning, in the south-western suburbs of London [neighbourhood of Wandsworth-common])? I have, I think, read somewhere that some of the old Bourbon Roses are suitable for such situations, and that *Sauvignon* is the Malmeson especially will thrive and flower well without manure; but none of the catalogues I have been able to consult seem to speak of *Sauvignon* de la Malmeson as a climbing Rose.—TYAN.

3632.—Rose "Climbing Niphotes" &c.—I shall feel obliged if someone will kindly inform me respecting the treatment of the Rose "Climbing Niphotes"? I have a plant of it grown in a border under glass since last May. It has made four shoots, 12-16 feet in length, and again these have broken into side-shoots in every direction. Two very inferior flowers bloomed about a month ago; there are two more buds now formed. Is it the height of this Rose to make wood and not to bloom? It is planted in a house where only Roses are grown. I ideal and W. A. Richardson have been discussing profusely, I generally have the climbers out back after blooming about May. Is this treatment right for the Niphotes? I have d'Or a good climbing Rose for indoor work?—L. E.

3633.—Which is the right boiler?—I should be greatly obliged if "B. C. G." or "J. C. G." or any other reader of *Gardening Illustrated* would give me advice as to the best and cheapest boiler? I mean when I say cheapest, that which requires the least fuel, as the cheapest as to the first outlay is not always the cheapest in the end. I want to heat a lean-to vinery. The piping would be about 250 ft. 4-inch. I know a few boilers such as Loughborough, Invincible, Horse-shoe, and then comes the coil, which my mind follows closely. There may be others which I know not, which may surpass even those I have named for cheapness and economy. I will just mention I have a Tortoise boiler which is only doing a third of what I shall require, so shall take out this one and add to the piping. The Tortoise has done the work fairly well, but uses a good deal of coke. The principle of it I do not like, as there does not seem enough heating surface, and much heat is lost up the chimney I think.—F. C. C.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3634.—*Ocloglyne orientalis* (H. R.).—The flowers came duly to hand, but there was a particle of soot more than I have noted to be the case with any other. I have never heard that the *Chatsworth* variety is scented.—M. B.

3635.—*Cattleya Mendellii* (H. G.).—I cannot say what has caused the plant to produce such bad flowers; but, from the fact of your saying it blooms upon the spikes are similar, I should be tempted to say it is through your own bad management. State treatment?—M. B.

3636.—*Madevalia Armini* (J. Fielding).—Your flower is a very fine form of this beautiful little species, the sepals being large and of a bright crimson-purple, each having a slender yellow tail nearly 2 inches long; this was introduced from New Grenada by Mr. Sandor, ten years ago, and it thrives well with the various *Odontoglossums* from the same country.—M. B.

3637.—Beef-suet-tree.—I am asked by "John Chambers" if there is such a thing? Yes, he is quite well informed; there is such a tree. Its systematic name is *Shepherdia argentea*, and it belongs to the Sea Buckthorn family. It is so called in the vernacular, I suppose, on account of the males which within the underside of the leaves are furnished. It comes from North America.—J. J.

3638.—*Cypripedium inaeigne* (E. J. B. B.).—All the varieties of this plant—and they now are very numerous—may be grown in a cold frame if kept moist, and they may be exposed to full sunshine, saving through the middle of the day. Plants thus grown will flower very late, unless they are subjected to a good heat in the autumn.—M. B.

3639.—*Dendrobium Falconeri* (Mrs. E. F.).—This appears to be the name of the flowers sent. I should like to know if this plant has little knobby stems caused by the joints being swollen? If so, it is the species named above, and is a native of Assam and Khasi. It has always been a somewhat rare plant, and some years ago it was very scarce.—M. B.

3640.—The Loakey-moth.—E. F. F. sends me a broset of eggs of this moth, asking what they are? The English name I here give; its systematic name is *Clitocampa neustria*. You had better be careful not to let your trees, and out each nest of eggs through, so as to get them off the shoots, put them into a box and so as I am doing with those sent me—that is, cremate them, for this caterpillar is one of the most destructive insects to fruit-trees. It lives in large nests upon the trees, and completely strips them of leaves; when one tree is done they migrate to another, then, of course, all the vigour and strength of the tree is expended. I do not wish to exterminate the broset, but I should like to know how to preserve them from destruction.—J. J. LEINOS AT

3641.—*Oclogyne cristata* (E. J. B. B.).—I do not know if the Chataworth variety of this plant flowers in summer or not, and if your plant is showing spikes of bloom now, it certainly will be flowering late in the spring; but are you sure they are not grown instead of flower spikes? The temperature is a sufficient one. Yes, they enjoy the sunshine, but must be shaded during the hottest part of the day.—M. B.

3642.—*Brassavola Digbyana* (A. M.).—This plant is somewhat a shy bloomer, but it has a wonderful flower, which has opened with me upon several occasions, and, if you wish it to do so with yourself, you should pot it the same manner as I have pointed out for a Leslie or a Cattleya, and grow it in the East Indian-house, and rest it in the cool end of the Cattleya-house. The plant comes from Honduras.—M. B.

3643.—*Oncidium macranthum* (G. Jones).—You should not destroy the buds on your plants simply to get the name. The two sent are not of the least use for that purpose, and you have deprived yourself of about 8 inches of flower-scape by doing so. Some six weeks hence, if you then want a name, I shall be very glad to give it; but what do you think you will do with the buds sent? But you will perhaps be too chary of the flowers to cut them.—M. B.

3644.—*Odontoglossum Ruckerianum* (H. W.).—This is the name of the variety sent. You may be as well pleased with it as if it had turned out the true Alexander; it is a beautiful spotted form, and I have noted that these natural hybrids are freer bloomers than the kinds which we here at home designate as apocles. Of course it thrives under just the same treatment as the true form of O. Alexander, being found growing together, it naturally would.—M. B.

3645.—*Insect in garden soil* (John Bargiel).—The insect you sent is the grub of the common Cockchafer (*Melolontha vulgaris*). These grubs are most destructive to the roots of many plants. I cannot suggest any remedy but turning them out of the ground wherever you can find them, no insecticide of any kind. What for a plant flags for no apparent reason it is always well to examine the roots as far as one can, and often one of these grubs will be found to be the cause.—G. S. B.

3646.—*Oroidiontine* (A. N.).—I am pleased to find you have been so successful in blooming *Oclogyne cristata*, especially as you appear to have so little accommodation for them. You should grow beside *Oncidium tigrinum*, *Odontoglossum Rossi majus*, *Lycaste Skinneri*, *Anulosa Clowesi*, *Maxillaria grandiflora*, and *Sophranitis grandiflora*. All these, I think, would do with you; they might want a little humouring to get them to take to your treatment, but afterwards all would be well.—M. B.

3647.—*Epidendrum fragrans* (K. J. B. B.).—Can you have this plant true to name? Why do you ask if it is a hybrid? If you have the true plant it was imported and flowered in England considerably more than a hundred years ago. You will see it figured in the *Botanical Magazine*, t. 1893, and it is found all over South America and in many of the West Indian Islands. I should ascribe the cause of your plants losing their leaves either to an overdose of water or too great exposure to the sun.—M. B.

3648.—*Odontoglossum* (J. B.).—The four varieties named will all do together; they require shade such as they would get in a north house, kept very moist in the summer, but less water on the stages and floor in the winter. They must have air, but it must not be admitted so freely as to dry up the moisture, and in the winter the temperature should be kept about 43 degs; through the summer the house must be kept as cool as possible. Your other two plants require a drier and brighter atmosphere than the *Odontoglossum*.—M. B.

3649.—*Dendrobium chrysanthum* (T. James).—This is the name of the specimen sent, and no name, but I take Roloboch's authority for its being distinct. Your flower is a very good form of the species; but anemostium is a different thing, being larger, and with a deep blackish-purple velvety stain at the base of the lip. Your plant is flowering at its right season; the one you thought it to be flowers nearer midsummer. Both plants come from Burmah.—M. B.

3650.—*Oclogyne pandurata* (J. Elphinstone).—The flower you sent is of this species, either a poor variety or badly done. Perhaps you have starved the plant. I used some thirty years ago to find it a very difficult plant to grow; but in the time we were striving for the cool system, and this plant will not put up with such treatment, it being imported from Borneo by the Messrs. Low, of Clifton, a little over forty years ago. It comes from near the coast to that country, and therefore you cannot well give it too much heat and moisture.—M. B.

3651.—*Pleione leaves turning brown* (K. J. B. B.).—I should think these plants must have been dry at the roots, or at least, must have been subjected to a very dry atmosphere, or perhaps to both. It appears to be a very bad case, and cannot but have a bad effect upon the bulbs, that are forming; but if you maintain a careful supervision over them through the season the many recover. They like sun and light, but from their thin membranous leaves it may be at once inferred they cannot stand the sunbake full upon them during the whole day.—M. B.

3652.—*Cypripedium hirsutissimum* (Miss M.).—Yours is a good coloured form of this beautiful species, which was first sold in Stevens' rooms for a new species of *Cypripedium*, many taking it for C. igneum. It was shown first by Mr. Parker, then a nurseryman at Wotton, and from this fact it was thought that he forwarded it first; but I had seen it past its best previous to this. It comes from Northern India; but I think the Messrs. Low imported their plants from Burmah, and from the richness of the colour in your flower I should think it was one out of the same batch.—M. B.

3653.—*Vanda Ameliana*.—A. N. asks me "How do you account for a plant of this species throwing up a flower spike, which, after growing a inch, and a half, suddenly stopped and gradually withered away?" Well, if the doctor comes to see you when ill, he has an opportunity to judge of your appearance, ask you sundry questions, and is able to prescribe for you; but you require me to state a case without seeing the individual who has been treated, the state of the atmosphere since last Christmas,

the temperature, or anything about it; but I should say, speaking in the dark, that the latter was too low and the former too wet.—M. B.

3654.—*Dendrobium nobile* (Tay.).—The flower you sent is a very good one as regards shape, but it is a very light coloured form. The question you ask—in what way *nobile* differs from *nobile nobiliss*?—could not have come at a better time, for I have a flower of this latter variety on hand, just in the nick of time; it measures 4 inches across, and the petals are over an inch in breadth, and the colour of the sepals and petals is deep crimson throughout, the lip large, stained in front with a large blotch of crimson, and then comes a zone of white, the base stained with a deep blackish purple velvety blotch; magnificent is far too poor a word to use for it.—M. B.

3655.—*Dendrobium flowers fading*.—J. Butcher says: "Can you tell me why these flowers fade so quickly? I put the plants as soon as they open into the flowering-house, so that it is not used by them getting wet. No, this probably is not the case, but I know it is a common fact of the plants to move their plants into the flowering-house, which I keep much drier, under the impression that the blooms will last longer; but I have frequently said that the plants should be allowed to remain in the house where they open, and I have proved it twice without number; but the flowers should on no account be wetted with water from the syringe.—M. B.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton Street, Strand, London, W. C.

Names of plants.—Mrs. Scarlett.—Cannot name from leaves only.—A. N. H.—Send both Ferns again when trends are fertile.—Odonto.—It is one of the forms of *Odontoglossum odoratum*, coming near to the variety *hexabotum*.—B. Castle.—1, *Vanda tricolor*; 2, *Oncidium fuscocinctum*; 3, A form of *Maxillaria variabilis*; 4, *Odontoglossum Pescatorei*.—J. Dugan.—Specimen too much shrivelled.—C. White.—1, *Madevalia ignea*, a good ordinary form; 2, *Lycaste Harrisonii* alba; 3, *Odontoglossum giorium*; 4, *Cypripedium Boyallii*.—F. B. B.—*Rhodoendron ferrugineum album*.—C. J. A very good flower of *Dendrobium Delhoussianum*.—M. White.—Yes, it is a very good form of *Odontoglossum Ruckerianum*, but not sufficiently distinct to name.—T. W. A.—*Vanda*; 1, *Vanda Ameliana*; 2, *V. tricolor*; 3, *V. tricolor insignis*.—M. S. Douglas.—Cannot name from crumpled up leaves only.—Calan No. 13.—*Fuchsia procumbens*.—J. D.—1, *Prunus Padue*; 2, *Berberis stonophylla*.—G. T. G. R.—Looks like *Prunus Padue*, but too much shrivelled up to determine the name accurately.—X. Constant Reader.—1, *Santolias incana*; 2, *Indigoferet specimen*.—Jeanette Potemayn, *Coleyva Bay*.—*Sparmannia africana*.—H.—*Acer platanoides*.—Robert Greening.—*Berberis stonophylla*.—Mrs. Hutton.—*Polygonum cuspidatum*.—Olney.—*Berberis stonophylla*.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

New Shop.—Apply to Mr. George Monro, Salesman, Covent-garden-market, London, W. C.—F. Oliver Hughes.—Apply to Mr. J. Groom, Seaford Nurseries, Geopfort, Hants.—A. Adcock.—The *Cineraria* leaves are attacked with the grubs of the *Marguerite Daisy-fly* (*Phytomyia affinis*), and the only thing to do is to pinch the leaves wherever the insect is seen to be at work and so destroy it. Some of the worst affected leaves had better be picked off and burnt.—Robert Greening.—The *Wallflowers* appear to be of a badly saved mixed strain. We have often seen *Wallflowers* "sport" in this way, and do not think the soil has much, if anything, to do with it.

Catalogues received.—Choice Exhibition Pansies, Messrs. Albert Morris and Co., Carlou, Ireland.—*Dahlia*, *Chrysanthemum*, *Bedding Plants*, &c. Messrs. J. Cheal and Sons, Crawley, Sussex.—Catalogue of Fries. Messrs. E. H. Krelage and Zoon, Haarlem, Holland.

POULTRY & RABBITS.

3656.—Poultry breeding, &c.—Will someone kindly inform me the best published authority on poultry breeding and diseases?—Marsu.

3657.—Blood in the yolk of eggs.—I always attribute the presence of blood spots in eggs to forcing the birds too much. First-class layers, such as *Microras*, if fed too well, are likely to overtax their egg-organs, and thus bring on some temporary derangement. In such cases it is best to feed lightly for a time, or change the birds to a fresh run, and thus check laying. When there are blood-streaks in the yolk, I should say the eggs have been sat upon, so that incubation has commenced.—Doulton.

3658.—Poultry-keeping.—Yes, it is much better to keep only one cock with your hens, as having several cocks would take away from the value of the eggs when required for sittings. You must not be distressed at not having many eggs at first; hens will not lay for four or five days in a fresh place. They must be given plenty of pounded mortar, or what is better still, oyster-shells, to form the shells of their eggs. Now that the winter weather is here, and there are plenty of grubs and insects about, your fowls will not need

more than two meals a day. The first meal should be soft food, scraps from the house mixed with Barley-meal or sharps, and in the evening, before going to roost, a good meal of grain, either Barley or Indian Corn. Go on feeding them till they cease to roo when the food is thrown at a little distance, but no longer, as it is then clear that they have had sufficient. It is most necessary that they should have fresh water given them every day; the vessels should be properly rinsed out at least twice a week. Yes, there are white *Minoras*. Your white hens might possibly be *Leghorns* if they have short yellow legs, but otherwise, if their legs are brown and white, they are probably *Minoras*.—Poka.

J. DERRICK'S Cheap Plants, Carriage Paid.

- ALL STRONG PLANTS a. d.
12 Roses on own roots, 11 to 15 ft. High. Hols. Hombr.
Rive d'Or, Arab. Carriere, Sir. Parson, Fierice, Mar.
gottin, Sour. d'Elise, &c., 12 var. List free. . . . 4 8
6 *Dentula gracilis*, strong, 14 ft. high . . . 2 3
6 *Mira Sinking Pinks*, strong clumps (12 for 1s. 6d.) . . . 1 6

CRYSTAL PALACE GRAND SUMMER FLOWER SHOW.

THURSDAY AND FRIDAY, MAY 11th & 12th. Schedule put free on application to—Mr. W. G. HEAD, Superintendent Gardens Dept., Crystal Palace, S. E. ENTRANCES CLOSE ON THURSDAY, MAY 11th.

PROFITABLE TOMATO CULTURE.

MY JUSTLY CELEBRATED TOMATO PLANTS are now ready, and if anything, finer and better than ever. No rubbish, but the very best varieties and selections only. Grand reports received from all parts of the country.

CONFERENCE.—The earliest, dwarfest, and best variety for small houses, frames, or open air, a rare sport, fruit medium size, and of delicious flavour. Strong plants, 2s. per dozen.

FIELD GEM.—Rather larger than the last, though not so large and coarse as many, but best and quickest grower, best of dropper, most solid and most deliciously flavoured Tomato in cultivation, will produce 50 to 60 lb. of fruit per plant, in all ground. H. W. Wagon, Esq., Shaldon, writes: "I shall grow nothing else." T. G. F. Esq., Felkstone: "I find Gem is all you say, and though they were surrounded by other plants all diseased (Challenger worst of all) only one took a few spots." A. S. per dozen. Three good plants for 1s. 6d. per or 4s. per dozen.

PERFECTION, a spicid strain; fruits 1 lb. to 1 1/2 lb. each, grand for exhibition, 1s. 6d. and 2s. per dozen. Blenheim Orange, 1s. 6d. 2s. per doz. all post free for cash.

TOMATO CULTURE BOOK AMATEURS, acknowledged by all to be by far the best work on the subject, 1s. 2d., post free.

B. C. RAVENSCROFT, Field, Crawley, Sussex.

TEA PLANTS.

AN ENTIRE NOVELTY.—The true Tea Plant (Thea) a pretty evergreen shrub with white flowers, easily kept in a greenhouse or window. Nice young plants, raised from seed, imported direct from Ceylon, 1s. 3d. and 1s. 6d. each; 2 for 2s. 3d. with instructions. A few extra strong, from single pots, 1s. 6d. each; or sent in pots per Parcel Post, 2s. Cultural Directions and List of choice *Begonias*, *Fuchsias*, &c., with each order.

B. C. RAVENSCROFT, Field, Crawley, Sussex.

FANCY PANSIES.

The following 12 grand varieties, 5s.: Thee Hussy Jane Barlow, Louis Wier, D. Bernis, A. H. Murray, Duchess Mabel, Lord Tennyson, E. Patterson, H. Eckford, A. Smith, D. Thompson, Miss E. Hunter. 1 offer 14 exhibition varieties, 3s. 6d.; Mrs. Freeland, D. Storie, Maggie A. Scott, Helen Patterson, Agnes F. Borrowman, Leam of Green, Mrs. M. E. Brown, Duchess Portland, My Lady, Nell Gille, George Gomb, Mrs. L. Cagney, Robert Stobbs.—A. BAILEY JUN., Pembury Grove, Sunderland.

TRAFFICANT NIEL, 3 Gloire de Dijon, and 3 other grand flowers, for 5s. 6d.—LEWIN & SON, 10, St. Martin's Lane, W. C.

GARDENING ILLUSTRATED.

FERNS.

SHADING FERNS.

FROM now onwards throughout the summer months the shading of Ferns is a subject for consideration. It is a point in Fern culture that is far too frequently carried to a great excess; the inference is arrived at without due thought that just because some Ferns thrive best with shade, others also must necessarily do the same. Far from it, however, for on the whole the opposite might be said to be the case. When shading is employed, particularly if it be at all dense, the growth of the plants is in the majority of cases considerably weakened; this is further aggravated by the adoption of permanent shading during a period of dull weather. The result is a soft, flaccid growth, which in the case of such as many of the Adiantums is further seen in enlarged pinnae. This, in some instances, as in the case of *A. Farleyense*, may look very well, but it is not of such an enduring nature as one would desire. Again, where a

HEAVY SHADING is upon the plants when not required, the result is an excessive atmospheric moisture, which is not easily dispelled without additional fire-heat, simply because the temperature does not rise sufficiently high to effect this desirable purpose in the case of all Ferns, the Filices excepted. Then ensues a period of damping off amongst such stove Ferns as the *Cymogrammas* and many others where the growth is dense. *Adiantum cucurbitum*, instead of retaining its fronds intact, will under these conditions go off in the same fashion when thick and the plants themselves too much crowded together. Where permanent shading is used at all it should be of as light a character as can be employed with safety. Do not on any account smother the glass as if whitewashing a wall or a ceiling, but lay on the mixture as lightly as possible, or employ the thinnest of shading material, which is of the two the better medium. During a period of cloudy weather, but all the more so when rainy as well, the damping-down and watering require to be performed in a careful manner, with a considerable diminution of the former part of the work. If done in a perfect fashion, with no distinction between hot and dry weather as against the opposite extreme, it must not cause any surprise if the Ferns soon suffer.

FERNERIES composed of rockwork arranged in an artistic manner, with the plants turned out, are often placed in positions where shading by means of blinds is next to impossible. In such cases the shading should be of the lightest kind, if really used at all (for in some instances none need be applied). All depends upon the distance from the glass, or whether climbers other than Ferns have been allowed to drape the roof. If the house be a tall one, there will be less danger of injury from scalding, while the climber, as well as adding to the effect, also serve a good purpose in intercepting any possible ill effects from the solar rays. It is a somewhat popular notion that Tree Ferns require a considerable amount of shade, but this is a mistake in the

case of most kinds. I can point to instances where none whatever is used, and where huge plants of *Dicksonia antarctica* thrive most luxuriantly. *Cysthea dealbata* and *C. medullaris*, also *Cibotium regale* and *Alsophilla australis*, can be grown in large houses without shade with safety as long as they do not come into contact with the glass. *Dicksonia squarrosa* and a few other tender kinds are safer if shading is employed. Of the smaller growing Ferns, there are a few of the Adiantums which are very sensitive to full exposure to the sun's rays, such, for instance, as *A. trapeziforme*, *A. curvatum*, and *A. cardiochlamis*. These should always be carefully looked after. On the other hand, exposure will in many cases intensify the beautiful roseate and bronzy tints peculiar to many Ferns, particularly the

ADIANTUMS, the shades of colour of which when the plants are shaded are not nearly so beautiful. It pays to keep all such Ferns grouped by themselves, the interest enhanced in their increased beauty being ample compensation for any little additional trouble. All Ferns which are grown more particularly for decoration either as plants or for cutting should be well exposed so as to ensure an enduring growth. One often hears the keeping qualities of the Maiden-hair Fern condemned when the fault more often than not is in its management. When grown cool, well exposed to light, and in an airy house or pit, it makes all the difference between lasting and fading; more so even when the precaution is taken to immerse the fronds for a time in water before use. In a mixed fernery the taller or tree varieties will often afford sufficient shade to those which may perchance require it without resorting to any artificial means whatever. Filmy Ferns, of course, require shading. For these I would recommend to have that of a permanent character, to avoid any risk of injury either from exposure or from sudden fluctuations in temperature, the one being as injurious as the other. *Gleichenias* are not nearly enough grown; these need but little shade. So treated, their fronds are far more enduring, although not perhaps quite so large in their parts, thus making most suitable plants for decoration. Neither the *Nephrolepis* nor the climbing Ferns will bear too much exposure.

CLIMBING FERNS.

LYGODIUMS.

THESE are singularly beautiful Ferns, and very free-growing. The fronds increase in length indefinitely, and remain permanently on the plants. They abound in the eastern tropics, and extend to New Zealand. They are also found in Mexico and Brazil, and one species has been found in Florida and Massachusetts, in the northern hemisphere. Lygodiums form beautiful objects in a fernery, being extremely useful as rafter plants, for clothing pillars, &c. These plants should be potted or planted out in a mixture of light loam, leaf-mould, peat and sand, but they must have good drainage if they are to succeed. They like an abundant supply of water to the roots, and during the summer months sprinkling overhead morning and evening will

suit them admirably. This latter should not be done whilst any sun is shining upon them. The following known kinds are worthy of cultivation. *L. articulatum* is a native of New Zealand, and although members of the genus are found throughout the tropics, the present species is not found anywhere else saving on Norfolk Island. It is abundant through the Northern and Middle Island, frequently growing 50 feet and 60 feet long, forming, we are told, dense screens in the forest. The sterile pinnae are each from 1-inch to 3 inches long, rich green on the upper side, often quite glaucous on the lower side, the fertile pinnae contracted, somewhat fan-shaped. This is very suitable for the cool fernery. *L. flexuosum*: The pinnae of this are divided nearly down to the base, are 6 inches or 8 inches long, deep shining-green above, paler beneath, fertile fronds contracted, bearing the fertile spikes in close rows. This is found in many places through the Malay Archipelago, the Philippines, Ceylon, &c., and consequently requires the stove. *L. japonicum* is another species which thrives well in a cool-house, and I once saw it used as a dense leafy screen between a warm house and a cool house. It is a handsome growing plant, from Japan and various places in the East. The Japan form makes an elegant little climber. *L. venustum* has deeply lobed segments of a rich bright green. I have never seen a fertile form of this plant. *L. palmatum* is a species from North America, and is usually considered hardy; it is an interesting plant, but growers are very apt to be misled by its being called hardy. It differs from the other species in seldom making fronds more than 18 inches long, and I have never seen it with fronds exceeding 2 feet. The fronds are palmate, usually three to five or seven-lobed, the colour being bright green. The upper part of the frond for about a foot is occupied by the contracted fertile fronds. It forms a handsome plant on the rockery of the cool-house, where it will drape the rocks beautifully.

3617. — **Canna-seed not growing.** — The temperature mentioned is not sufficient to raise these plants with any degree of certainty: they require a strong hot-bed of 80 degs. or 85 degs. If the seed was thoroughly fresh and good, and had been soaked before sowing, it might, however, have germinated; but the ordinary seed of commerce is not to be depended upon—at least, such is my experience. All you can do is to take the seeds out of the soil again, and if they appear still sound, re-sow them in fresh, sandy soil, and plunge the pots in a strong bottom-heat. It is, however, very doubtful if they ever germinate now.—B. C. R.

— Some six weeks ago I bought a collection of the new hybrid Cannas. The seeds were soaked in warm water in the way I usually treat Cannas, for twenty-four hours, and were then sown in pots of warm soil in a Cucumber-house. I think we have now about half-a-dozen plants up out of 400 or 500 seeds. The conclusion I have come to is that, there being a large quantity of seeds of these hybrids, a little doctoring had been done.—E. H.

GARDEN WORK.

Conservatory.

Young, growing, hard-wooded plants may have a shift now; it is well not to overdo. The drainage must be perfect, and in sufficient quantity to allow surplus water to pass away freely. All the fine half rooted plants must have good point, enough clean dead being mixed with it to keep the soil open. Firm potting is essential, and sufficient space must be left at the top for water. Most of the plants will have received what pruning was required some time ago, and the young shoots will now be making some progress; but if the pruning has been omitted better wait now till the roots are working through the new soil. All hard-wooded plants are the better for a little pruning. I generally prune Epacris and Acacia considerably; but other plants of the different genera grown are pruned more or less, as each case seems to require. Hard-wooded Heath and Azalea do not generally require pruning. All newly-potted plants should be kept a little closer for a time, and a thin shade during the hottest part of the day will be beneficial. Outtings of Abutilons and Eupatoriums may still be struck for growing on. Of course, the worm, oley pit is best for the work. Fires may be discontinued now—at any rate, while the present bright weather lasts. However, the furnace and flues thoroughly cleaned, so that the fire can be lighted quickly if required. The weather still out-comes wonderfully hot and bright for the season, and plants rush into bloom and fade sooner than usual. Light shades to temper the strong heat will be drainable, unless the roof is heavily covered with creepers. Large boxes which are difficult to work blinds upon may be made quite comfortable by a free growth of climbing plants dangling about. Veronias in variety, and the autumn-flowering subjects; mirlings of V. and some of them will soon root and will make flowering to off in 6-to. pots in the autumn. This variety will do well in the shaded house, as it is as early as possible hardy. Agapanthus are now throwing up flower spikes. This old plant, when of large size, is very attractive, and might be more common, as so much can be made of it, both indoors and outside. A large mass in a tuft that will stand out on the lawn is always effective, and the abetter of a cool-house in winter is all that is required. Forced Lilacs of the candium type will now be pretty well over, but L. Harlowi is coming into the ground in a cool conservatory. Very useful are the Stationers when grown to a good size. Liquid-manure will increase the size of the blossoms, but it must not be used very strong. Isthemic guano or Oley's Fertiliser, half an ounce to the gallon, will be strong enough.

Unheated Greenhouse.

Those just making a start with a new house may gather all the information they can about suitable plants for walls, pillars, &c., and get them planted now, this being the best season for doing so, as the growth being made and well ripened up before winter will stand more frost. I am referring more especially now to those things which have a certain amount of tenderness in them. Many of the Chinese and Japanese plants, and some of the Australian plants, will do with only the protection of a glass roof. Tea Roses are always available for covering roofs or walls, but we do not all like the same tints, and more variety is wanted. Camellias planted in a suitable soil will flourish to a charming manner the back wall of a lean-to house. Myrtles, again, can be utilised in various ways. Lycopodium alba and rosea will be best planted in a bed of peat in a shady position. Arnoldi Donax variegata also does much better planted out in a cool-house. Give it room enough and it forms a handsome specimen.

Stove.

I am still putting in outtings of Polioceles. Where anything of a stock is required it is hardly possible to get all the outtings at once, and outtings struck now or even later will make very useful stuff (6 to 8 inch pots); besides, it is better to have some plants later in producing their heads of bracts than others. I like to see a few of the white variety mixed with the scarlet. A group of the latter, with a plant or two of the white form dropped in round the margin, heightens the effect. Caladiums will now be in splendid leafage if the syringes is used. Only soft water should be used for the least time, and give the leaves a smudged appearance that will detract from their value for decoration. There is an increased demand for those pretty-foliaged, tropical Asparagus plants, commonly called by those who do not care much about correct nomenclature Asparagus Ferns. Very pretty is A. plumosus scandens climbing up a pillar or against the back wall of a stove or any other warm house. The plants do not increase very fast by the usual methods of propagation; but seeds, when obtainable, will soon work up a stock. Pans filled with Klintonia are charming for many decorative purposes, and are easily propagated and grown to a suitable size. Panicum variegatum is useful for growing in small pots to margin shelves and stages, or to fill in round the bottom of baskets in which Ferns are planted. Outtings of the points of the shoots put in now will soon root.

Mushroom-house.

Unless the house is in a very cool position it will be better to make Mushroom-beds outside now, either placing the north side of a wall or sinking them in a trench below the ground level. A cool place is the most suitable. Make a clearance of all old beds which are exhausted, and remove the remains of Spakale roots, Rhubarb, &c. Give liquid-manure to beds still in being, and maintain a humid atmosphere by damping walls and floors.

Orchard-house.

Regular treatment will be necessary, and to make the most of the sunshine. My usual course is to take off about half the ventilation at 3 P.M. and close finally at four P.M., using the engine to give the trees a good wash at the same time. Very closely glazed houses might have a chink of air along the ridge of the house in the evening to be kept on at night, but usually more or less ventilation gets in through various openings; but under any circumstances air should be given by six o'clock in the morning, to be increased as the temperature rises till full air is on. I look upon ven-

tilation at this season as a most important item of management. Finish thinning the young shoots, and if there are more fruits on an tree than they ought to carry, when ripening, remove them at once. Why permit trees to carry a heavier load, even for a short time, than is necessary? Liquid-manure may be given now two or three times a week, and a little rich compost should be placed over the surface of the soil when the trees are in pots.

Pits and Frames.

Bedding-plants may have full exposure now during the day, but should be covered for a little longer at night. There will soon be plenty of empty pans and pots now, which may be utilised in various ways, some being planted with Tomatoes, Cucumbers, Melons, Capelous, &c., and others prepared for growing on Cyclamens, Primulas, Clovearias, Tree-Carnations, &c., in.

Window Gardening.

Get all window-boxes put into proper repair and painted. Where there are several sets of boxes, those intended to be filled with tender things to come in after the spring flowers are over may be covered and placed either on the greenhouse stage or in a pit or frame to grow and get strong, ready for the windows when the weather is suitable. In the windows inside the room do not keep old, useless plants. One well-formed plant is more effective than dozens of old, badly-grown subjects. This rule would apply everywhere—grow few plants, but care for them.

Outdoor Garden.

Hyacinths and other bulbs exposed to the full sunshine have been shorter-lived than usual this season, and there will probably be a chance of getting the beds prepared for the summer-bedding plants earlier than usual. When the beds are constantly cropped, more must be done in the way of manual top-dressings. The best dressing for beds from which bulbs and spring flowers have been cleared is a little earth, old manure, or old Mushroom beds well broken up will do mixed with the shared refuse from the rubbish-heap. The fine material will blend with the soil, and the roots of the plant will strike into it immediately. There is a very praiseworthy tendency nowadays to substitute hardy plants for the ornamental bedding stuff, and those who have adopted this plan find it a pleasant change. Of course, if a glare of colour is required, Pelargoniums, if the season happens to be suitable, will supply it; but in a wet time the Pelargoniums run too much to leaf and are not satisfactory. To mention only a few hardy plants suitable for massing, I will list the Hybrid Gaillardias. The plants sown outside last May will now be ready to go out, and they will commence blooming in June and continue till November. For late summer and autumn broad mass on the lawn of White Japanese Anemones has quite a distinct character, and everybody admires it. I have had masses 20 feet over that were very attractive. The red variety is also effective in its way. A mass 10 feet or 12 feet over of Lavender on the lawn is a charming object when properly managed, and it is not absolutely necessary that these groups should have a formal outline; but I think they look better when the Grass grows right up to the foliage, so that there is no bare margin. Have not space now to refer to other hardy bedding plants.

Fruit Garden.

Forced Strawberries were never better in colour or flavour than they are now, thanks to the bright sunshine; but the watering has been a very heavy business. The bright weather has enabled us to feed more liberally without doing harm. As soon as frames or pits can be opened clear, they should be covered with glass to give a clear start to fill in with fermenting materials, and put out strong plants of Melons as soon as the temperature is right. These plants will produce ripe fruit early in August. In several ways Melons are different in their requirements to Cucumbers. They must have soil with plenty of body in it—i.e., heavy loam, and they do best in a firm root-run. Do not bury the collar in the soil over much. In dull, wet weather this may be a cause of rot. A little air early in the morning now is necessary in all fruit-houses. When panes are closed at 8 o'clock in the morning, anything will grow, and it is more sure to be trouble some. During this bright weather be very careful with the Aes. I am letting the trees go out in the morning when the sun shines bright; placing the plants between two trees is not only a waste of fuel, but it does harm, as it necessitates much labour to maintain the proper humidity to the atmosphere, and if this is neglected the red-spider will soon put in an appearance. Continue disbudbing Peaches on walls, and use the Tobacco-powder where necessary. I should recommend that all fruit-trees on walls should be watered copiously, especially Apricots and Peaches. The position is a dry one, and the season, especially in the eastern counties, is unusually dry and hot. Look well after inside berdes of vineyards and Peaches. A more liberal supply of water will be required than is generally the case, and stimulants may be used freely where heavy crops are the rule.

Vegetable Garden.

To get up successional crops of anything in a dry, hot spring like the present, thoroughly soak the land before sowing the seeds, and shade afterwards till the seeds germinate. Seeds are sown in hot, dry soil without some preparation being taken, they will not grow all the same. Such a thing was never known before in April. One wonders where the growers' profits come from; but I suppose the hot sunbabe has rushed them on, and they must be got rid of in some way; but the job-trot way of the past would not have produced them. I suppose the cucumber benefits—i.e., if Cucumbers may be considered a wholesome article of diet. Spare frames may be filled with Cucumbers now, placing a little warm manure in the bottom to give the roots a start. Tomatoes in cold-houses are coming on rapidly, and require a good deal of attention

in regulating and stopping growth. It is not well in crowd, especially if it is attended to only at any time to be in. In good sized houses where the rows run across the borders 2 feet apart is a good distance, and the plants in the rows will do very well at 18 inches. E. HODAY.

Work in the Town Garden.

The protracted drought and almost tropical sun renders watering a very heavy business, both indoors and out, but it must be done, for without a due supply of moisture nothing can be expected to do much good at this season. A light shade on the glass reduces the labour of watering considerably, and prevents scorching, besides prolonging the beauty of the flowers. A movable shading is always to be preferred, but falling thin, a thin coat of white or lime-wash answers the purpose fairly well. Flour and water (not paste) made rather thick, and a very little whitening added, forms a capital shading, and, if the plants are not nearly transparent, is not readily washed off by rain, but is easily removed when necessary. Out-of-doors, all trees, shrubs, and plants that have not been in the ground long, and are still but imperfectly established, must be kept well watered, or they will perish to a certainty. The morning is the best time to water now, though an overhead shower early in the afternoon will also be advisable on hot days, but though we have had no frost to speak of, here in the south, at least, for the past week or so, the plants are still cold, and under such conditions the foliage at any rate ought to be dry. Newly-laid turf also must be regularly watered until it becomes established, and where Grass-seed has been sown this also will be all the better for a good shower with the hose or engine every two or three days. Late flowering herbaceous plants, such as Michaelmas Daisies, Chrysanthemums, Christmas Roses, Pyrethrum uliginosum, &c., may still be divided and replanted, but keep moist subsequently. Thin out hardy annuals already up, and sow a last lot for late flowering. Cases of will be the best for a cool house, such as the Cornflowers, Marigolds, Sunflowers, Annual Chrysanthemum, and a few others will stand a lot of drought unharmed. Lose no time in sowing Asters, Stocks, Zinnias, Phlox Drummondii, &c., on open borders; these must be kept moist and have good, rich soil. Plant out shrubby Calceolarias without delay in deep, well-manured soil, and keep moist. The more forward batches of bedding plants should now be removed to cold pits or frames to be hardened off, and Dahlias also. Shift Tomatoes for outdoor planting into 6-inch pots, also any for which space cannot be found under glass at present. Pelargoniums coming into flower must have weak liquid-manure about twice a week; very the character of the fertilizer as much as possible. In the outdoor garden Acoriolas are very beautiful just now; this is the right time to sow seed in a cool frame. Tie up the stems of Carnations loosely to neat sticks. B. C. H.

THE COMING WEEK'S WORK.

Extracts from a garden diary from May 6th to May 13th.

Moved plants from a house to pits and frames to harden them off for the flower-beds; those plants which have been out some time have been shifted a stage further on to open places where covers can be used at night. The proper hardening of the foliage has a good deal to do with their early effectiveness when placed in the beds. Plants turned out with softer foliage through being imperfectly hardened by gradual exposure will certainly suffer. Another thing that should be looked to is to prevent the roots working through the bottom of the pots into the bed in which they may be standing. If taken from such a position with the roots suddenly broken, the plants will die, and very probably the edges may turn brown. Picked off early sown Primulas, and potted off Cyclamens, Balsams, and Cockscombs. Sowed Chinerias, Bearraged conservatory. The climbers have rather stolen a march on us lately, and only a few days' delay at this season means entangled growth and extra work. Pelargoniums are now a special feature, and include a good selection of show and floral, Zonal, and those with scented foliage. These last are always popular. They add rather more than their share to the garden, and do not do much harm to the plants. After the bulk of the Pelargoniums are over will come special features in Fuchsias, Gloxinias, Achimenes, &c. This will be in addition to the usual greenhouse plants in bloom at all seasons. Tied down, stopped, and removed laterals from Vines in various stages of growth. In the early house when the Grapes are colouring the laterals will be allowed more freedom for a time. Though this may be carried too far, and by encouraging late root action prevent the Vines getting the necessary rest. Still a little more fling to the roots of sluggish Vines, or even if not sluggish, will do good if not carried too far. Apricots have set thickly under a double thickness of fishing-net, and some of the smaller where much crowded in clusters have been thinned. The fruits are quite large enough for use in the kitchen. I have had to water many things, chiefly those late transplanted, including fruit-trees, new beds of Asparagus, &c., and the Peaches and Apricots on a south wall have had a good soaking from the pond, and a light mulch placed round the trees as the position is very warm and dry, but without doing much harm to the plants. After the bulk of the Pelargoniums are over will come special features in Fuchsias, Gloxinias, Achimenes, &c. This will be in addition to the usual greenhouse plants in bloom at all seasons. Still a little more fling to the roots of sluggish Vines, or even if not sluggish, will do good if not carried too far. Apricots have set thickly under a double thickness of fishing-net, and some of the smaller where much crowded in clusters have been thinned. The fruits are quite large enough for use in the kitchen. I have had to water many things, chiefly those late transplanted, including fruit-trees, new beds of Asparagus, &c., and the Peaches and Apricots on a south wall have had a good soaking from the pond, and a light mulch placed round the trees as the position is very warm and dry, but without doing much harm to the plants. After the bulk of the Pelargoniums are over will come special features in Fuchsias, Gloxinias, Achimenes, &c. This will be in addition to the usual greenhouse plants in bloom at all seasons. Tied down, stopped, and removed laterals from Vines in various stages of growth. In the early house when the Grapes are colouring the laterals will be allowed more freedom for a time. Though this may be carried too far

TREES AND SHRUBS.

CLIMBERS FOR ARCHES AND WALLS.

CHINESE KIDNEY BEAN-TREE (WISTARIA SINENSIS).

This well-known climber is so hardy and such a rampant grower, that success seems assured by simply planting it and leaving it to take care of itself afterwards; but a little art and care bestowed upon it much improves its beauty. When the Wistaria is used for covering the side of a house or for a shade to a piazza or archway, as shown in the annexed engraving, some definite system of training should be adopted in so far as to decide what piers or columns of the piazza or archway are to be covered, and whether the plant is to be trained along the cornice or to be carried yet farther upward to screen a window. When this is done, and the necessary rods or wires have been provided, the proper shoots for the use required should be selected, and thereafter all others that may interfere with the

be treated in the same way as those of the previous year, and so on year after year. By following this course of treatment long continuous wreaths of flowers will be produced. When the leading stem or stems have reached the length it is intended they should attain they should also be stopped, and the final effect will be an orderly and trim appearance of the plant, which yet must not appear stiff and formal. Treated thus, the Wistaria may also be grown on the lawn, or as a specimen plant in the shrubbery, either on single stems or on ordinary shrubs with several stems. H.

Deep coloured Flowering Currant.

—There is a variety of the Flowering Currant known as *atro-rubens*, in which the flowers are very much deeper in colour than those of the ordinary form. In *atro-rubens* both the individual blooms and the racemes in which they are borne are smaller than in the case of most of the others, but they are produced in such

others, but when the best is obtained it is a really handsome shrub. The leaves of this last are deeply lobed and of a glossy green tint, so that it is throughout the season very ornamental. In the whole of these *Ribes* the foliage is retained well throughout the summer, and it is rarely attacked by insects. —H.

RUBUS SPECTABILIS.

EXCEPTION is at times taken to this *Rubus* on the ground that in some situations it may become a perfect weed; but much the same remarks will apply to many other beautiful plants, the object of the gardener being as far as possible to find the spot most suitable for them where their charms can be seen to the best advantage without interfering in any way with their neighbours. The *Rubus* in question is a native of North America, and is a free, upright-growing species that from the profusion of suckers soon forms a large mass, and reaches a height of 6 feet to 8 feet. The drooping blossoms, which are borne in great numbers, are bright purple; a tint but little represented among outdoor shrubs. This *Rubus* is the first of the genus to unfold its blossoms, which open about the same time as those of the Flowering Currant, so that there are really very few shrubs then in bloom. It is better adapted for the wild garden or a spot where the conditions are unfavourable to a plant at all delicate in constitution than it is for highly-cultivated ground. This *Rubus* will hold its own in hot sandy soils, and also succeed far better than most shrubs under the shade and drip of trees. The next species to bloom after that above mentioned is *R. deliciosus*, a beautiful shrub, and one well worthy of a place among the most select. This, which is totally devoid of spines, forms a much-branched bush, clothed with lobed Currant-like leaves, and about May it is profusely laden with pure white blossoms like single *Roseae*. *Rubus nutkanus*, with large lobed leaves and pure white blossoms, is another Bramble for which a place may often be found, and much the same will apply to *R. odoratus*, whose flowers are purplish. Towards the latter part of the summer the most conspicuous of all the Brambles are the two double-flowered forms, white and pink, but more especially the latter. In this, the blossoms, which are borne in great profusion, are composed of a number of closely packed quilled florets of a pleasing shade of pink colour. As they are at their best when most shrubs are over, and will succeed in soils that are of too dry and sandy a nature for many things, these Brambles well merit a word in their favour. During the winter season, when quite devoid of foliage, one species stands out quite conspicuous from any of the others by reason of the stems being of a silvery whiteness, which, associated with other things, may tend to form a striking winter picture. This Bramble is the Himalayan *R. biflorus* or *leucodermis*, a strong growing, rambling kind. T.

Wistaria sinensis on an archway.

design to be carried out should be vigorously cut away. A system of pruning nearly similar to that of the spur system in Grape-Vine pruning should then be adopted—or rather, a method combining that with the system generally adopted for fruit-trees which bear their flowers and fruits on old spurs. The Wistaria, though a climbing plant, like the Grape-Vine, produces its flowers from old spurs like a Cherry, a Plum, a Pear, or an Apple-tree. In the month of July all shoots or eyes on the main or leading stems that may be reserved should be pinched back to within a foot of the main stem in order to check the rampant growth. These shoots will again break into growth from the buds just behind where the shoot was stopped off, and after they have grown a few inches in length they should also be stopped in the same way. The result will be the formation of flower-spurs at the foot of the shoot first shortened. Early in the succeeding spring these shoots are to be cut back to within five or six eyes of the main stem, and the young shoots from these eyes are then to

numbers and are so brightly coloured, that the difference in size is only noticed on close inspection. This variety is by no means common, though it has been known for many years—indeed, it is one of the few varieties mentioned by Loudon. In making a selection of the most distinct Flowering Currants, there may be noted, in addition to the above, albidum, with large clusters of bluish-white blossoms; glutinosum, whose leaves are destitute of down, and flowers of a pinkish-lilac shade; flore-plena, very interesting and pretty on close inspection, but at a little distance it does not present any particular noticeable feature, except that it is later in flowering than any of the others. The form known as Gordonianum, which is supposed to be a hybrid between the ordinary Flowering Currant and the golden-flowered *Ribes aureum*, must have a place among the best, as its orange-red flowers are distinct from those of any of the others. Lastly, there is the golden-flowered Currant itself, some forms of which are superior to

3623.—**Superphosphate and nitrate of soda.**—Although I have about 200 yards run of Cordon Apple and Pear-trees I cannot undertake the responsibility of recommending you to use either of the fertilisers you mention for the trees without I knew more of their condition than your inquiry furnishes. Not knowing how long they have been planted, or the kind of soil they are growing in, or whether they are promising to give a crop of fruit this year or not, it would be unwise to advise you to apply the manure you mention. There is no doubt your trees would be benefited if their roots had a good soaking of water this dry weather. —J. C. C.

—The former is a fine grey powder, and should be sprinkled on the soil round the trees at once, and lightly pricked into the surface with a fork. A hundredweight will be sufficient for about a quarter of an acre of ground, and unless rain comes shortly it should be well watered in. The safest and best way to use the nitrate is to dissolve it in water, 1 ounce to each gallon, and give the trees a good soaking with the solution when the soil becomes moderately dry, though, as a rule, two or three applications during the season will suffice, as this substance promotes growth rather than blossom or fruit, and if applied in excess will do more harm than good. —J. C. C. CHAMPAIGN

FRUIT.**BEST GRAPES.****MUSCAT OF ALEXANDRIA.**

THOUGH one of the oldest of cultivated Grapes, this Muscat is still at the head of the list of white Grapes in respect of both flavour and appearance. It requires a little more care and

It is mistaken economy to stint the fire if it is really needed, and during the time the bunches are lengthening out and the blossoms expanding there must be a generous warmth from 65 degs. to 70 degs. at night to make sure of the blossoms setting well. It is well also to assist the setting when the pollen grains are ripe and active, either by shaking the trellis or drawing a soft hair brush lightly over each bunch, or by

Grape "Muscat of Alexandria."

skill to bring it up to the highest possible condition as regards that beautiful amber tint of colour and high finish found in the best examples than such varieties as the Hamburgh, Alicante, and Sweetwater; but when the roots are kept within touch and the Vines treated generously, there is no special difficulty which may not be easily overcome by those who think out their position and carry out promptly the lessons taught by the changeable conditions under which gardeners have to work. By generous treatment I do not mean that the border should be lavishly manured. I believe more Vines, Muscets and others, have been hopelessly ruined by using strong farmyard-manure in the borders than by any other cause. Keep the roots in a healthy medium, and the interior management must be wretched indeed if the Grapes are not fairly good. Judging from my own experience, I should say Muscets require a firmer, heavier loam than Hamburghs to bring out their best points. That the Muscat of Alexandria has a vigorous constitution is proved by the number of old Vines still doing good work in many old gardens in this country. Given a suitable treatment, preferably partly inside and partly outside the house, not too circumscribed in extent, nor yet so large nor deep as to place the roots far away from solar warmth in summer, the growth inside to have room to strike out and not trained too near the glass, especially if the house is of modern construction—from 16 inches to 18 inches is a good distance—there should be no difficulty in obtaining good Grapes. Close stopping or pinching is not wise. There must be a good breadth of foliage, but overcrowding of young growth is ruinous. Wherever there is space to fill it will be better to disregard the orthodox advice to pinch at the first or second leaf beyond the bunch. Let the Vines occupy all the space, but do not overcrowd the leaves. In the matter of work, one good substantial leaf is better than two or three small thin ones. Again, in the application of artificial heat, do not expect the same result as the making of saving the proverbial "hearth of tan"

the adoption of any other expedient which experience teaches is best calculated to secure a good set. The annexed illustration represents a good example of a bunch of Muscat of Alexandria Grape. As regards stimulants, most cultivators use something, either in the shape of top dressing or in a liquid form, and if the horders are well made and properly drained, it pays to be liberal and generous in the matter of sustenance when the Grapes are swelling. II.

Pruning Figs.—This is undoubtedly the best time to prune Figs out-of-doors, as it can now be seen which shoots are best furnished with young fruit, these being, as a matter of course, retained. Cut as many of the old shoots out as can be dispensed with, training those retained at from 6 inches to 8 inches apart on the wall, being careful to allow sufficient room in the shrod loops for the individual shoots and branches developing themselves. By pruning the trees just as they are pushing into leaf the risk of injury through bleeding incurred when the trees are pruned at an earlier date is avoided. I have followed the above practice during the past twenty years with very satisfactory results in the way of crops. Of course, a judicious system of thinning and stopping the young growths during the growing period is essential to success. Lay in one young shoot between each pair of last or previous year's growths, stopping these at about 2 feet, and pinching all superfluous shoots hard back to allow of the light reaching those retained.—W.

3576.—Vines in a cool house.—You may begin to dishud the Vines as soon as the young growth is long enough to handle, or, in other words, it is a good plan to remove all but two shoots from each spur, finally choosing the one to remain that shows the most promising bunch of Grapes. When this shoot is brought down to the wires the other one may be removed. The object of leaving two shoots for a time is because there is some danger of their snapping off from the spur as they are being brought down. For this reason the young growth

should not be brought down to the wires all at once. In a general way Vines require to be gone over and tied down about three times. If you stop the shoots at the third joint above the bunch three ties will be ample, the last tie being given just before the flowers open. After this you must keep all the lateral growth pinched back close to the shoot below the bunch, and at one joint above that point. Do not be tempted to overcrowd your Vines because they show a good number of bunches. If you want to avoid the berries shanking, and to insure the Vines remaining in a fruitful state, one large bunch of Grapes to every foot of raftar, or two small ones, is all they should be allowed to carry. Remove ugly shoulders from the bunches, and thin out the berries as soon as they can be handled. Vines have started early this year, even in cool-houses, therefore there should be no difficulty in ripening the crop; but as we cannot tell what the subsequent weather may be, it will be wise to make good use of the sun's warmth now by closing the house early enough in the afternoon to cause the thermometer to run up to 90 degs. or 95 degs. Give a little top-air early in the morning, and damp the floor and walk three or four times a day in bright weather.—J. C. C.

3611.—Vines the first year.—Try to keep the side shoots not less than 12 inches nor more than 18 inches apart. The dishudding will have been done before this. Stop each shoot two leaves beyond the bunch. I have occasionally left three leaves where there was room enough, and I have sometimes been compelled to pinch back to one; but two leaves seems about the happy medium. Tying down to the wires must, of course, have careful attention.—E. H.

— The length at which the side shoots ought to be stopped depends very much on the space available at the side of the main rod. If the Vines are not planted nearer than 3 feet from each other, and assuming that the best bunches on the Vines shows at about the third joint of the side shoot, then the point of the shoot ought to be removed two joints above the bunch. Another guide is this: Allow as many main leaves to develop as there is space for between the main rods, but do not overcrowd the foliage. One fully developed leaf is of as much value to the Vine as half-a-dozen that is weakened by overcrowding. Therefore, in some cases it may be right to pinch the shoots above the second leaf, and in others at the third. In a day or two after stopping the side shoots lateral growths will spring from the nodes. These should be pinched at the first joint. Suhlaterals will also grow. These are best removed entirely by pinching with the finger and thumb. If the side shoots are 1 foot apart on each side of the main rod they will have then sufficient space for free development of the foliage.—S. P.

— Act on the principle of the more leaves the more roots, and therefore the more roots the Vines can make this season the stronger they will be next, is the plan I advise you to adopt. In the first place select the strongest shoots on each side of the cane and let them form five or six leaves before you pinch off the tops. The flower-bunches (as you call them) should be removed at once. If the Vines are vigorous the side shoots will form fresh growth. This must be pinched back to the first or second joint. The leading shoot on each Vine may be allowed to grow to the top of the house before you pinch off the top—unless you find the lower shoots are not making satisfactory progress. In that case stop the leader at once, and let it form another; this will divert the sap into the lower branches. If the roots are in an outside border and have not been watered, let them have a good soaking at once from a pond or open tank, and immediately after lay on a mulch of half rotten manure 4 inches thick.—J. G. C.

3610.—Training Peaches.—By the aid of stout galvanised driving-eyes, an inch long, fixed in every other course of bricks, 6 feet apart, thus having wires threaded through the holes every 7 inches or so apart, according to the thickness of the bricks, a capital trellis can be made by anyone. No. 8 galvanised wire answers well for tying the branches to. If the wall is long one, a stout support ought to be fixed at one end, and the wall, Angle iron, an inch wide, fitted with belts and nuts, will be

necessary to keep the wires tight. The wires ought to be almost close to the wall, allowing just enough space for passing the tying material between the bricks and the wire. If a wide space is allowed the tree do not receive benefit from the warmth of the wall, but a draught is created; this is harmful to the trees.—S. P.

—Peaches can be trained on strained wire on a garden wall. 15-gauge wire will do, and it may be taken diagonally up and down the wall, so as to form diamonds. This gives greater facilities for training than if the wires are strained horizontally, though the latter will do very well for all trees except Peaches. The wires should be strained on round-headed, galvanised nails driven into the wall at suitable intervals. To make the wires form diamond pattern, the wall will have to be gone over twice, working the second set of wires obliquely in the opposite direction. The wires for Peaches should be closer than for other trees.—E. H.

3624.—Strawberry flowers.—Frozen Strawberry blossoms do open with black centres, and I have seen the same thing happen when the plants have been allowed to get very dry so as to injure the young roots.—E. H.

ROSES.

ROSES AND THE WEATHER.

WE are surely passing through one of the most extraordinary seasons for Roses that has ever been recorded. At any rate, I cannot remember anything like it before. In a recent number of GARDENING, I mentioned how I saw the White Banksian Rose in flower in the open air in the West of England at the end of March. A week later I saw in another garden that beautiful old Rose, Réve d'Or, with scores of well-expanded flowers upon it, and hundreds of buds on the point of opening. Gloire de Dijon was well in flower on warm walls in many gardens before the middle of April, and in warm, sunny corners the old Pink Monthly Rose was quite plentiful. But in my opinion Réve d'Or takes the first place as the best early flowering Rose. The plant to which I refer was, indeed, a sight worth going a long way to see, and made me wonder why people will persist in planting Maréchal Niel, which is rarely satisfactory, while there is such a reliable and beautiful variety as Réve d'Or, which grows well in all ordinary soils, and produces a plentiful crop of flowers both in the spring and autumn. As I write, the weather is tropical in character. The abnormally high temperature, and the surface of the ground as dry as dust, is not exactly the kind of weather that rosarians require, and should the present climatic conditions continue, the dates of Roses shows will have to be altered to an earlier period to meet present circumstances. At no time in my experience do I remember when Roses required the soil over their roots mulched so much as they do this season.

THE DROUGHT has penetrated so far down that only those who water freely and mulch heavily can expect to get a good show of flowers. With regard to mulching, I do not know of a better system than that practised by Mr. Baker, of Exeter, who is well known as a successful exhibitor of Roses. This gentleman gives the roots a good soaking of water first, and then covers the surface soil with a thick layer of manure, and on the manure a thin coat of earth is spread. This is obtained from between the rows of plants. Insect pests are likely to be very numerous, and none more so than the green-fly, and in this connection I must say a good word for the house Sparrow, as I know from observation that these birds consume good numbers of these insects, as only to-day I have watched them amongst my Roses and seen them go from branch to branch, clearing off the flies as they went. I am not an admirer of the Sparrow generally, because he eats my early Peas and devours my neighbour's corn; at the same time I must confess that the harm he does is balanced by the good in the number of insects that he destroys when we do not touch his appetite with young and tender Peas and ripening corn. It is, however, not advisable to wait for the birds to clear off our enemies. The simplest remedy that can be used for all Roses that are within reach is to dust the affected shoots with Tobacco-powder; but the most certain plan of killing the flies is to dip the shoots into some soapy water, or in the case of climbing plants to syringe them with the liquid.

Soft-soap, dissolved at the rate of 2 ounces to a gallon of water, will kill every insect it reaches. But neither this nor any other liquid application will be effectual if it is applied when the sun is shining or the wind blowing, as in either case the liquid would be dried up before it has time to do its destructive work. J. C. C.

CLIMBING ROSES.

FOR pelous, pillars, arches (see illustration), arbours, walls, sides of houses, and high buildings, &c., only those Roses are suitable which have more or less of what is called a climbing habit of growth. Roses which make long rambling growths, whose shoots are unable to stand up without support of some kind, these are the kinds which do duty as climbers. Before determining on the kind of climber to plant, however, the height the plants are required to attain must be considered. Most of the vigorous Hybrid Perpetuals and Teas may be relied on from 8 feet to 15 feet if the soil be good, and on warm, sheltered walls 4 feet or 5 feet higher. The extra strong growers of the same classes, with the Noisette and Hybrid Noisette, will cover well up to 15 feet or 20 feet or more. The Banksian Roses are excellent as climbers, but should only be planted against walls in rather sheltered positions; they are only summer bloomers. The white and yellow may be both relied on up to 30 feet in good soil, but the large white will run much higher. This kind is evergreen, except in very sharp winters, which is a great recommendation, but it is not so prolific in its blooming qualities as the two first-named varieties. The old Blush and Crimson China Roses will also run up the face of a wall freely to a height of 30 feet, and, as before stated, for continuous-blooming qualities they are unsurpassed by the varieties of any other family of Roses; indeed, they are frequently out at their best when inexorable frost sternly interposes and checks them; in spite of this, however, it is not unusual to find a few buds still unfolding at Christmas-time. The old-fashioned summer-blooming Roses before alluded to are capable of almost anything in the way of height; probably in good and deep soils they would climb in a very few seasons, if

and to take off unripened ends. Climbing Roses away from walls should not be planted in very exposed positions, or, as a rule, they will fail to gratify the cultivator. Climbing Roses may be used to screen unsightly buildings and other objects, by training them to galvanised wire or other fences or supports, and, except when the leaves are off, answer this purpose most admirably, by the interposition of their loveliness. All the above methods of growing these Roses not only yield good effects, but give supplies of flowers for cutting. Heretofore, however, I have not mentioned Moss Roses, because, from an ornamental point of view, in the outdoor garden, as growing plants, their value is comparatively small. As cut flowers, however, they are among the most exquisite of Florists' productions. E.

Early Roses.—"J. C. C." in his notes on Roses in GARDENING, April 22nd, page 95, mentions that several flowers of the White Banksian Rose were cut from a plant in the West of England on the 31st March. He may be interested to hear that this Rose, or rather the yellow variety, was in flower in the South of England at the same time. At Easter I was staying at Worthing, and on the Tuesday (the 4th of April) I walked through the little village of Sompting, some two miles off, which is noted for the curious Saxon tower to the church. The village lies in a very snug position at the foot of the South Downs, and on the houses I noticed the Yellow Banksian Rose in full bloom, and I have no doubt that they were so on the 31st of March. The climate of Worthing seems very suitable to the cultivation of various plants, and the amount of land in its immediate neighbourhood now covered with glass-houses is enormous, and is still increasing. From passing glances at the houses, they seemed chiefly to contain Vines, Cucumbers, and Tomatoes. The well-known Fig-gardens at Tarring, a village close by, being another proof of the mildness of the climate.—G. S. S.

3632.—Rose Climbing Niphetos.—Yes, it is the habit of this Rose to grow luxuriantly the first year and not produce many flowers, but if you have patience you will get plenty of flowers next year on the wood it is now making.

Rose arches.

well tended, any ordinary church-steeples. They completely cover themselves with blooms during the blooming period, if rightly treated, and all the treatment they require, if in good soil, consists in tying them to their supports, pruning out weak and exhausted wood, and encouraging to the utmost such vigorous young shoots as may be required. No growths need be shortened, except to keep them within the bounds allotted to the plant,

If you require large blooms the young shoots must be trained out 6 inches or more apart. Personally, I like to cut the plants back the same as you have here in the habit of doing, but I think you had better adopt the let-alone plan for one year, and see how you like it. I shall be disappointed if you do not succeed with this Rose to your satisfaction.—J. C. C. You have treated your Roses excellently, and I am glad to see that William Allan

Richardson have flowered freely with you, I can only imagine that the wood of Climbing Niphedea did not get sufficiently matured last autumn; it is a later grower than the two other varieties you name. I have found it very free blooming, but not quite so much as W. A. Richardson. You are quite correct in cutting the plants back now, or as soon as their crop of blooms are over. Revo d'Or is not one of the best Roses for indoor culture. It grows too strong, is apt to be almost overgrown, and seldom ripens under glass sufficiently to produce a full crop.—P. U.

3661.—**Climbing Roses for a house wall.**—A north-east aspect is not suitable for the better forms of Roses. Gloire de Dijon (fawn colour) will, however, do for one; Félicité Perpétué (creamy-white) is also quite hardy, and Sir Joseph Paxton (rose) is also suitable. If there is much space to cover, the Ayrshire Roses will do it sooner than those I have named, only the quality of the flowers is not so good. The best of these are Dundee Rambler (white) and Splendens (flash colour). The Garland (fawn) is one of the most Bessie, and a capital grower. You are right about the character of Souvenir de la Malmaison in so far that it will thrive and flower without much sun; but it is not a climbing Rose, and, therefore, not adapted to your purpose.—J. C. C.

I am afraid "Tyro" will scarcely be successful in growing Roses on a north-east wall, and so near to London. Souvenir de la Malmaison is not a climber, but, like almost all Roses, it can be used as such for low walls, &c. If "Tyro" means to try a few Roses I can recommend the following as being those most likely to suit his position and locality: Cheshunt Hybrid (red), Gloire de Dijon (buff), Sir Joseph Paxton (red), Coupe d'Hébé (pink), Madame des Tartas (red), Boule de Neige and Coquette des Blanches (white), while the best yellow is likely to be Tour Bertrand.—P. U.

ORCHIDS.

LÆLIA ELEGANS.

Blossoms of two or three varieties of this plant come to hand from "G. Ellis," and I would here caution my readers about sending flowers, and it should be borne in mind that blooms cut on Saturday morning, packed in a dry wooden box, are not delivered until Monday morning, and they lay, consequently, a day and night in the office in London, which does not add to the lustre of their flowers, so, once for all, I would say do not send me flowers either home direct or to the office on Saturday, especially if you want an opinion respecting them. My present contributor wants to know if I do not consider one of these a good dark variety of elegans, but I cannot so flatter him that it is a dark variety at all; but it is certainly a very dark-lipped and good form of the light varieties, the sepals and petals being flushed with rose, and the whole front lobe being of a dark crimson-maroon. The other two flowers are fairly good varieties of the typical form, and which are usually seen blooming at this season. Now such forms as L. præstata, L. Morreniana, L. Bromiana, and L. Turneri and some others which I could name, and which I have seen so fine in the Woodlands collection at Streatham, all seem to flower in the autumn months, and these light varieties mostly open their blooms in the spring and early summer. This Lælia is supposed to be of hybrid origin, and certainly I do think from the variability in the plant there is much ground for the supposition; but then there are some forms called elegans which I do not think have anything to do with that plant, for, irrespective of colour, there is so much difference in the shape of the lip, an item I have always looked upon as being of special importance; for instance, there are L. Wolstenholmie and L. Schilleriana, which some consider as merely forms of elegans, but which would appear to me to be totally different. But I hope my friend, Mr. Seden, will soon set the minds of us all at rest by letting us see what he can raise by cross-breeding under artificial means. Well, all I can say further to "G. Ellis" is that the flower sent is a very good one; but it is not a dark variety. It should be potted, as I have so frequently told my readers, in good peat fibre and some chopped Sphagnum, and the pots must be well drained, and the plants should stand at

the hottest end of the Cattleya-house, because they like a good deal of heat when they are growing, and also a moist atmosphere, and they do not like to be dried very much in their resting season either. MATT. BRAMBLE.

THE WHITE MOTH ORCHIDS, WITH A NOTE ON PHALÆNOPSIS APHRODITE.

The flower sent by "A. Calder" is a great beauty, and I am not surprised that my friend has obtained this under the name of P. amabilis. Now this is one of the errors made in naming the plant when it first flowered in this country, which occurred in the then celebrated nursery of the Messrs. Rollisson's, at Tooting, and it was mistaken by Dr. Lindley for P. amabilis, which had been known to science some time previously, and so the mistake was perpetuated in our gardens; but the true amabilis is the plant which is generally known in our gardens as P. grandiflora, and for its introduction we are indebted to the Messrs. Veitch, of Chelsea, who had it sent to them when at Exeter by Lobb, and from the plant specimens have been sent by "Mr. Calder." It is distinguished by its larger and lighter green leaves and by its usually larger flowers, and in the shape of the lip. P. Aphrodite has oblong, deep-green leaves, which beneath are of a deep purplish hue, and flowers of a pure white, the lip also being white, more or less marked with purple at the base and marked with yellow. It is a magnificent plant when done well, and it keeps a very long time in perfection; indeed, the flowers will last far too long for the well-being of the plant and should, therefore, be cut, after, say, a month or six weeks are past, by which means the plant is relieved of the severe strain put upon it by the large amount of blossoms, which have been called white Moth-flowers. Now, how to grow these plants successfully is one of the reasons why "Mr. Calder" has written to me, in order that I may enlighten him somewhat. Well, this is always a delightful task, and one in which I sometimes am successful, as letters, which I from time to time get from my readers, testify. Well, to grow Phalænopsis is very simple and very easy, requiring only a little care and attention. The first thing I contend for is a house which has ground for the floor instead of stone or a concrete pavement, because then there is a gradual moisture from the earth always arising which is highly beneficial to the plants. This may be planted sparsely with dwarf Ferns or other low growing plants. The house should also have plenty of piping, so that in cold weather, when artificial heat has to be depended upon entirely, there need not be any hard driving of the fire. Shading must be carefully attended to, and the sun should never be allowed to shine upon the plants, although I like the house to face the south. Well, now I think everything that is necessary has been said about the house, saving, perhaps, the ventilation, and this must be good. The temperature should never fall below 65 degs. at any time. The plants may be grown in baskets or in pots. I like the former the best if they are substantial, and, therefore, would advise these to be of earthenware, shallow, and well drained; and for soil use just a very little Sphagnum Moss over the roots. This must be taken particular notice of, as upon this matter so much depends. Combined with the above instructions, a moist atmosphere should always be maintained, as without this black thrips become the worst pest that can befall a grower of these plants. I subjoin some of the more popular kinds beside the one, P. Aphrodite, named here.

P. AMABILE, which is the old plant popularly known as P. grandiflora, flowers large pure-white, stained at the base with yellow. P. Luddemansiana: Flowers medium-sized, ground colour yellowish-white, thickly marked with bright purple transverse bands, lip bright-purple. P. Marie: This is a lovely gem, the ground colour being yellowish-white, handed with chestnut-brown; the lip is rich, deep purple. This was introduced by Messrs. Veitch and Sons, of Chelsea, but we have to thank the Messrs. Low, of Clapton, for rendering it comestible to the majority of growers. P. Schilleriana: This is just like a rosy-pink P. Aphrodite, a real gem. There are several forms of this plant, all of which are really worth careful attention. P. Schilleriana: This species

was first introduced to German gardens, and it flowered for the first time under cultivation just thirty-three years ago. I have frequently had hundreds of flowers of this plant expanded at the same time, which gives one a very good opportunity of marking their variations. In an ordinary way the flowers are rosy-purple, and the three-lobed lip is also of a bright purple, with a yellow crest, which is spotted with red, and instead of the long, slender tendrils this plant has a lip resembling the tail of a black cock, and, besides, it has beautifully-spotted leaves. D. Stuartiana: This is thought by many to be a natural hybrid, having spotted leaves like Schilleriana and a flower of the same shape. It, however, has white flowers, having the lower half of the petals spotted with reddish-purple. All these plants are natives of the Philippine Islands and others in the Indian Ocean. Other fine kinds are Sumatrana, violacea, speciosa, tetraspis, Lowi, and many other smaller species, including many varieties, but all require about the same treatment. MATT. BRAMBLE.

3630.—**Loam for Chrysanthemums.**—If the loam is passed through an inch mesh sieve before using it for potting the plants into 3-inch and 4-inch pots the work is much facilitated, as pieces of turf that will not pass through a sieve of the mesh named are useless for potting into these small pots. If the turf is chopped well first with the edge of a spade it is easily passed through the sieve, and without the loss of any of the fibres. In placing the plants in 5½-inch pots I do not recommend that it be sifted, but chopped sufficiently fine. When dealing with the final potting into 9-inch and 10-inch I sift all the loam that is of a heavy, retentive character, but this time a sieve with ½-inch mesh is used. My reason for this is that heavy loam is more liable to become inert, and consequently less porous, when the fine soil is left also along with the fibrous parts. Instead of pulling it to pieces I chop it with a spade into pieces 2 inches square. Lots of fine soil is sure to be present even in doing this much. The ½-inch sieve relieves the knobs of the fine soil, and thus the compost maintains its porosity better. When placing the plants in all pots, except those in which they are to flower, I employ a portion of the roughest parts of the compost for covering the rocks. In the case of the last potting, though, I use pieces of freshly-cut turf in addition entirely to the compost. By this means the latter is not robbed of its rough parts, and cannot become non-porous in the same way, as though it were all fine soil.—S. P.

3602.—**Wireworms and bulbs.**—The simplest and best way of getting rid of wireworms from among bulbs is to lay baits of something which they are fonder of than the bulbs, and to examine the baits three or four times a week, and kill the wireworms. Wireworms are very fond of the seeds of French Beans. I have scooped little holes in the borders, and dropped in half-a-dozen Beans, just covered them with soil, and marked the site with a small stick. In two or three days the wireworms, if they are numerous, will swarm in the Beans, and may be pulled out and destroyed. Other good baits are slices of Carrots and Potatoes. Persecution will certainly clear them out.—E. H.

3312.—**Lime-water and worms.**—Lime-water is not injurious to any kinds of plants except Ericas and Azaleas. These, as a rule, are not troubled with worms nearly to the extent that others are, owing to the compost being composed mainly of peat. Lime-water is of the right strength for use when the water will not absorb any more lime, but allows it to sink to the bottom, after that it is useless to add more. Do not pour the sediment from the bottom of the vessel on to the soil in any case.—S. P.

Lime-water should be used for plants in pots. It will be better not to give it to Camellias or Azaleas, as they dislike lime. Lime-water need not be used if one desires to get rid of worms on lawns, as the clear lime-water is not so strong as in the first instance, before some of the lime has been deposited. There is nothing safer than lime-water.—E. H.

3648.—**Getting rid of worms.**—Lime-water, if used of sufficient strength, will get rid of worms. If one wishes to get rid of worms on grass, it is best to use it until the ground is impregnated with lime, and then the worms will disappear.—E. H.

OUTDOOR PLANTS.

THE "EMPEROR" DAFFODIL.

This, one of the best and boldest of all the yellow Daffodils, was raised from seed by the late Mr. W. Backhouse, of St. John's, Wokingham, many years ago. To the same raiser we also owe the Empress Daffodil, and both were figured in the old *Floral Magazine*, wherein we are told that they were the results of crosses between *N. bicolor* and other forms of *N. pseudo-Narcissus*. Both *N. Emperor* and *N. Empress*, quite apart from the size and beauty of their flowers, are robust in constitution, and as a rule they thrive well on nearly all soils, bearing flowers at least a third larger than those represented in the engraving. The perianth lobes of *N. Emperor* are of a soft pale-yellow with a deeper golden trumpet, the whole flower being of stout substance and of the texture so well illustrated by the accompanying woodcut. Even although this fine free-growing kind has been in some points surpassed of late years by such fine seedling kinds as are *Gloire de Leyden* and *Weintraut*, yet for general garden culture it still remains one of the most distinct and effective of all good garden Daffodils. Like most other Daffodils, *Emperor* grows best in pure, deep tarry loam resting on gravel or other well-drained bottom. Nothing in the way of freshly added or crude manures should be given, but this variety and some other garden seedlings do well if planted in succession to a crop for which well-rotted manure was used.

PERENNIALS FOR BEDS.

1853.—There are a large number of things suitable for the purpose, and I have made a selection; but I advise you to get Robinson's "Hardy Flowers," which may be obtained at 37, Southampton street, W.C.; it deals fully with hardy plants for bedding, and gives hints for appropriate contrasts. Carnations would make a fine bed, but it is late now to put them out. A good bed of the brighter self-coloured flowers is one of the sweetest pictures one can get in a garden. Then you could select the *Treacle Lupine* (*Lupinus polyphyllus*) and its variety *alpinus*, both of which grow about 3 feet in height. The type has pleasing blue flowers, produced in summer, and those of the variety *alpinus* are white. The two planted together make an attractive contrast in colour. A fine bed would be made of the various kinds of Lily, the earlier blooming forms, such as the peculiar *Scarlet Turk's-cap*, *L. chalcedonicum*, the brilliantly-coloured *L. croceum*, *L. davuricum*, and its varieties, which seldom grow more than 2 feet in height, and *L. candidum*; but the majority are rather too tall for your purpose. Very charming is a good bed of *Pentstemon*, and they will live through ordinary winters without harm. When

in full bloom a bed of these is graceful and showy, as the flowers are produced freely. *Campanula persicifolia* (blue) and the variety *alba* are two good kinds, each about 2 feet in height, and very beautiful when in perfection. A glorious bed could be made of *Lobelia fulgens*, selecting such varieties as *Firefly* and *Queen Victoria*; the flowers of each are very bright crimson in colour, the spikes tall, and the leafage dark bronzo-chocolate, a rich contrast of colour. A good bed of either variety would be very rich,

it grows from 18 inches to 2 feet in height, and is sometimes known as *R. speciosa*. *Helenium pumilum* is another good hardy plant for a bed. It was used effectively massed together last year in the Royal Gardens, Kew; the plant is hardy, easy to grow, and about 18 inches in height, being covered in the summer and early autumn months with a mass of golden-yellow flowers, each about 2 inches in breadth. A lovely flower for a distinct bed is *Anemone japonica alba*, or *Honone Jobert*, the flowers appearing in late summer and lasting in beauty until the late autumn. It is a mass of pure-white, and gives plenty of bloom for the house without destroying the beauty of the bed. A good deep rich soil and ample moisture are the chief considerations. It need not be disturbed for several years, but allowed to develop in beauty without a common plan of constantly interfering with the roots. I like the white kind by itself, but you may have the rose type for contrast if you care for the association of colour. A good selection of double *Potentilla* make a show of colour, and a few varieties, such as *William Rollison* (scarlet, shaded with brilliant orange-yellow), *Le Vesuve* (vermilion, the petals with a golden edge), *Melpomene* (bright-yellow, with a shade of orange-scarlet), *Victor Lemoine* (deep-vermilion colour with golden blotches), and *Hamlet*, (velvety-brown, an intense colour, as amongst the more attractive.) The *Delphiniums* make a fine display, and these flowers have been greatly improved of late years, some of the newer kinds having spikes of bold flowers, each blossom of fine shape, colour, and size, the colours very deep and effective. A good bed of them would be very fine, but the plants grow to a considerable height, four or five feet, even more. A very beautiful bed could be formed of the best varieties of *Tufted Pansies*, which bloom throughout the summer, until the autumn in fact. *Archie Grant* (deep violet-purple), *Sky-lark* (white, edged with blue), *Ariel* (mauve, shaded with white), *Blue Cloud* (white, with a broad edge of blue), *Bullion* (bright-yellow, very free), *Countess of Hopetoun* (pure-white, very compact and free), *Countess of Kintore* (bluish colour, the edging brown and pink-white), and *Holy-wood* (deep blue). *Iris germanica* in variety would perhaps be too fleeting for you; but while they last the flowers are very fine, and give off a delicate Elder-like fragrance. A good bed may be made of the *Pyrethrums*, especially

OUR READERS' ILLUSTRATIONS: *Narcissus "Emperor."* Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. J. D. Pearson, Chilwell, Notts.

and the flowers appear in July, the height of the plants being about 2 feet. *Centaurea montana* and its varieties may be taken note of, as they are very bright and showy, the flowers ranging in colour from pure-white to deep-purple, and they last a considerable season in beauty. A bright, showy flower is *Coreopsis lanceolata*, and also *Rudbeckia Newmannii*, which bloom rather late in the season, but produces a wealth of rich yellow flowers, very rich against the centre cone of almost black colour

the double kinds, and a small selection would comprise *Andromeda* (purple-rose), *Aphrodite* (pure-white, very pleasing), *Aurora* (sulphur, the centre yellow), *Haage et Schmidt* (deep-rose), *Melton* (very bright-rose), *roseum plenum* (rose and white), and *Transcendent* (rich crimson). Then a bed may be well devoted to the early-flowering *Herbaceous Phloxes*, which grow, rising from 1 foot to 2 feet in height; they bloom freely, and bear flowers richly of fine size and colour. C. T.

3552.—**Flowers for a grave.**—As the soil is so heavy and clayey, it would be well to mix with it a barrowful or so of leaf-mould, burnt garden refuse, and fine ashes, before putting in the flowers, or they will not do well. A pretty edging might be made with summer-flowering *Ferret-me-Not*, nice sturdy little plants being used, with a tuft of *Golden Feather* between each if preferred. There are few more beautiful objects on a grave than *White Madonna Lilies*, but these must be sunk, pot and all, if wanted to flower this spring. *Gibber-wise*, a clump of these roots can be transplanted best in July (just after they have done blooming), and left untouched from year to year, when they will form a very handsome group. *White Tea Rose* (*Niphotes*, specially) are also suitable, but these, too, must be sunk, pot and all, at the present time, and can be planted permanently in October. *White Marguerites* may be used for the centre, with *Pansies*, *Mignonette*, and *Ivy-leaved "Geraniums"* round them. These last can be allowed to droop over the soil, covering it, with the other plants, completely. Of course there are many more brilliant flowers, such as *Scarlet "Geraniums"* and *Begonias*, which would make more show, but they are not in good taste here. *Lilies of the Valley*, and a few simple spring bulbs, such as *Snowdrops*, *Sollia sibirica*, and *Crocuses*, can be substituted for the summer plants in October. *Windflowers*, too (*Anemones*), can then be put in, and an edge of *Primroses* put in the place of the *Golden Feather*, with fresh plants of *Ferret-me-Not*. All these will flower in early spring. The plants now put in will require careful watering and shading for some time, if this drought continues.—I. L. R.

— I should think that you cannot do better than select bedders, such as the *Tuberous Begonias*, and if the grave is not very large, or a little additional expense is no object, the white-flowered kinds would be most appropriate. The plants could be put out about the end of next month, and they will keep up a show until out off by frosts; or you could get various colours, as the flowers vary from the deepest crimson to the purest white. The habit of the *Tuberous Begonia* is so dwarf that the plants would look well in such a position. Then there is the useful *Zonal Pelargonium*, which keeps a gay appearance throughout the summer with little attention. I should have some such arrangement as this: *Tuberous Begonias*, with the variegated *Dactylis* and *Blus Lobellias*, or you could have a fine show of *Tufted Pansies*, which will continue in bloom throughout the summer, and make a change from *Pelargoniums*. All these will succeed in the position mentioned, whereas the annual flowers—at least, the majority of them—require more sun, and they are apt to get ragged and unsatisfactory unless constantly attended to. In the autumn you could plant spring flowers, as *Daisies* and *Primroses*, with a careful selection of choice bulbs. You will then get a succession of bloom quite early in the year until frosts cut off the summer flowers.—C. T.

3544.—**Narcissus flowers dying off.**—This may be due to the bulbs being weak, or the position being quite unsuitable, but more likely through want of lifting. It is impossible to get satisfactory *Daffodils* if the bulbs are left undisturbed too long, and in many cases they are not divided for several years, and then complaints are rife they will not bloom satisfactorily. I should advise you to lift them as soon as the leafage has died down; divide them, and replant again early in the autumn in good deep soil. Once in every two years is the time to lift *Daffodils*, and they are really better for being lifted every year, as is the practice with the large growers for market. You must remember that the more robust varieties increase very fast, but otherwise they will gradually cease to bloom, and die. Possibly yours are in this condition, and require timely attention. Do not lift them until the foliage has died down.—C. T.

3545.—**Dahlias.**—Four good show Cactus kinds are *Juarazi*; *Mrs. Hawkins*, the flowers of a sulphur colour, the margin paler; *Henry Patriok*, pure white; and *Panthea*, reddish-salmon in colour, good Cactus-like shape. When showing *Cactus varieties* always have flowers of characteristic form, not like the so-called decorative half show and half Cactus.

Four show *Dahlias* would comprise *Mrs. Glodstone*, the colour very delicate bluish; *Harry Keith*, rose-purple; *R. T. Rawlings*, fine yellow; and *Glowworm*, orange-scarlet. As regards the fancy kinds, you cannot do better than select *Gaiety*, the flowers yellow, with stripes of red, and tipped with white; *Frank Pearce*, rose-coloured with stripes of crimson; *Mrs. Saunders*, yellow, the petals tipped with purple; and *Pelican*, pure white, with stripes of purple. Your other question is greatly a matter of taste. I have chosen of the Cactus kinds *A. W. Tait*, pure-white, and *Cochiseal*, rich-crimson, in which there is a tinge of brown; of the *Pompon*, *E. F. Juaker*, amber, and *Lelia*, red-buff colour, the petals tipped with white; and of the single class, *Duchess of Albany*, delicate mauve, the edge tinted with orange-red, and *Maudie*, pure-white, maroon edge. Get the mauve with the white or yellow, and the crimson with the same two colours, keeping crimson away from the mauve. A good idea would be to mass the crimson in the centre, yellow round it, then white, then mauve.—C. T.

Oorydalis nobilis.—This is a distinct and extremely taking rock plant. It is, I think, the handsomest of all the *Fumitorias*, of a robust habit, and yielding always an abundance of its striking flowers. It rarely exceeds 1 foot in height; the strong flower-stems, leafy to the top, rise from a mass of bright-green, Fern-like foliage. The flowers are of a rich golden-yellow, with chocolate spots on the lip. It is invaluable for damp spots in the rockery or border, and does best in a light free soil, to which has been added plenty of rotten leaves. It may be increased by division. *C. solida* is also in flower now, but neither so showy nor striking as the above. It forms curious tuberous roots, from which spring the leaves and flower-stems. The flowers are of a dull purple colour. This species should be planted in the woods. It is already naturalised in some parts of England, and as it stands both drought and shade well, I find it useful for planting near the trunks of deciduous trees, &c.—G.

3620.—**Creeper for a trellis.**—I should recommend *Berberis stenophylla*. It will do well in the shade, is always pretty, and grows freely on wall or trellis.—E. H.

INDOOR PLANTS.

3605.—**Deutzias in pots.**—Yes, it is usual, though not actually necessary, to cut these plants down rather hard as soon as the bloom is past, and then encourage a fresh growth from the base, to flower the following season. Market growers, who want plants in small (5-inch) pots only, cut their plants down almost to the soil after flowering, and encourage a vigorous growth afterwards by means of plenty of warmth and moisture. This being well ripened in the autumn flowers profusely the following season. If, however, large specimen plants are wanted, the growth should only be slightly shortened back and any weak spray be cut out; then when in growth again give a moderate shift, and in a few years' time fine large bushes, full of bloom, will be secured.—B. C. R.

— It is usual to cut out the old wood after the plants pass out of bloom, in order that the young shoots from the base may develop into flowering growths for the following season. If good specimen flowering plants are wanted it is an error to do this. I thin out the old growths, leaving a considerable number just as they are; a limited quantity of young growths being allowed to take the place of the older ones cut out. The larger proportion of the flowers are produced on the old wood. The plants should be repotted after flowering, and ought to be placed in an open position out-of-doors, sheltered if possible from the north and east winds. *Deutzias* root very freely, and need considerable supplies of water during the summer.—J. D. E.

— There is no necessity for cutting down plants which are well furnished; it would be a mistake to do so. But loose, straggling plants may be cut into shape, and afterwards bespiced in a close, warm pit to make new growth. Those plants which are well furnished and do not require cutting back may be plunged outside as soon as the young wood gets a little firm.—E. H.

3625.—**Hyacinths and Tulips.**—Yes, the bulbs will succeed if you treat them in the way you propose, providing you keep the boxes in a sunny position, and the soil moist at all times, until all the leaves die away naturally. They would no doubt flower better next year if they were planted in fresh soil. If you can do this early next September, by all means do so. When you have got the bulbs out of the soil remove any offsets, and plant them in good soil in the garden. In two years' time they will be large enough to flower. I was enriched the other day to see what a nice stock of bulbs a lady amateur had raised in this way. Some of her *Hyacinths* so treated had spikes of flowers equal to those that she had purchased. Plenty of manure is used in this garden, and a space is set apart on purpose for the young bulbs. It was evident, however, that she gave them unremitting attention.—J. C. C.

3627.—**Cyclamen culture.**—I suspect the plants are allowed to stand in the sun and often get perched at the roots during the time they are out-of-doors, or else they ought to do well. At the present time a frame stood behind a north wall is the best site they could have. Sufficient water to prevent the soil becoming quite dry is all that is required during the summer. When there is no fear of frost the plants may be stood clear of the frame, still under the shade of the north wall. About the middle of August, or before if new growth is apparent from the crowns, they should be potted, turning the roots out of the old pots, and removing most of the soil, transferring them to pots one or two sizes larger than in which they flowered before. A compost of three parts fibry loam, one of leaf-mould or horse-manure, with half a part of peat; a sixth part of dried cow-dung, or one quart of finely-ground bones, to every bushel of the compost, adding sand according to the state of the loam—heavy or light. Place the plants in the frame again, syring the foliage every afternoon, keeping the frame rather close for a week or so until new roots are formed, when abundance of air will be needed to keep the growth stocky. Attend regularly to the supply of water at the roots; on no account let them suffer for want of it. Toward the middle or end of September place the plants in a light greenhouse, as near to the glass as possible. Shade the glass during light weather for two or three weeks, and moisten the foliage in the afternoon daily. Weak liquid-manure applied to the roots every alternate watering will be an advantage. Upon the first appearance of green-fly fumigate the plants with Tobacco-smoke.—S. P.

— There is a very great difference in the size, &c., of the flowers, and often foliage as well, of these pretty plants, some "strains" being infinitely superior to others, and even from good seed the quality varies greatly. Old or neglected roots, again, are almost sure to produce small flowers. But the plants ought not to be kept "pretty dry" at any time; on the contrary, the soil should always be moderately moist, and the pots stood in a shady place during the summer. Repot them in July, using a mixture of garden loam with half as much of leaf-mould and peat, with plenty of sand, and keep close and shaded until established.—B. C. R.

3571.—**Salvia coccinea nana.**—This is a greenhouse plant, but in good summer, if put out when all fear of frost is over, it would bloom in the summer months. The best *Salvia*, however, for the garden is the beautiful *S. patens*, which has very bright blue flowers, and they are produced freely, so as to make a good effect. It is used largely for the centres of beds, and is sometimes planted in a distinct bed with happy results. The *Ageratum* should not be used to fill one bed only, but it is a very good plant for associating with other bedders, as *Fuchsias*, *Tuberous Begonias*, &c. The *Zee* is one of the best kinds. The plant is dwarf and compact, and the flowers are of a fine blue colour.—C. T.

3618.—**Treatment of a Myrtle.**—The only way I can help you is to beg of you to be patient with your *Myrtle*. No doubt it is too young to flower. If, however, it is an old plant, and of a size that should flower, you may help it to bloom by getting the growth better ripened, or if the growth is weak, give it a larger pot at once. Then stand it all the summer in a sunny position in the greenhouse, and give the roots plenty of water in hot weather.—J. C. C.

ACHIMENES AS BASKET PLANTS.

THERE are few plants that are more showy and useful, or afford such a variety of colour and form of flowers, as the different kinds of Achimenes, the habit of which is such as to render them equally suitable for growing in pots or baskets, although it is in, perhaps, the latter way (as is well shown in the annexed engraving) they show themselves off to the best advantage. In order to prepare them for this purpose it is a good plan to start them first in pans of leaf-mould or finely-sifted peat, from either of which they lift readily, and transplant with large balls, and may then be distributed regularly to furnish the baskets. The latter made with wires about 1½ inches apart answer the purpose well, as between these the heads of the plants may be thrust as the filling up proceeds. The quickest way, however, is first to line the baskets with Moss and then put in the soil, when, by making

frames, kept shaded and shut up early; but till then they must have artificial heat to get them along. Throughout the summer they require abundant supplies of water; but it is essential for their welfare that it pass freely away, for anything approaching a stagnant state of the soil is sure to throw them out of health. Except green-fly and red-spider, Achimenes are not much subject to insects, and the first-named pest can easily be got rid of by fumigation with Tobacco, which, however, should be done cautiously, as it does not take much to injure the tender foliage. For the red-spider the best remedy is the diligent use of the syringe and clean, warm, soft water to the foliage. Should mealy-bug attack them, as it occasionally does, then it must be removed by the use of a small brush or sponge. After they go out of flower they require no further special care, and may be wintered anywhere under

rose-coloured flowers; A. Manve Queen, mauve-coloured flowers, a very fine, large-flowered kind; A. patens, fine violet, the flowers large; A. picta, flowers yellow and scarlet, a dwarf-habited species from Mexico; A. Pink Perfection, magenta, shaded with violet, carmine eye, flower large; A. Rose Queen, purple and rose, with yellow throat, very compact habit, profuse bloomer; A. stella, magenta, spotted with carmine, orange eye, flowers serrated on the edge; A. Williamsi, vivid scarlet, large flowers, compact branching habit. D.

3608.—**Double Cinerarias.**—This is a case of reversion from double to single flowers, an occurrence that is not unusual in Cinerarias whether the plants are raised from seeds or offsets. It is possible that you have unwittingly assisted the plants to revert back by growing them in too rich soil, or giving them strong liquid stimulants. I am, however, inclined to think that the high temperature which we have had this spring has something to do with it by hurrying the plants into flower. In a general way the double varieties do not bloom so early as the single ones.—J. C. C.

—The Double Cinerarias do not, as a rule, become single, and if propagated year by year from offsets and grown in good soil there is no alteration in the character of the flowers. If the plants were grown in poor soil the probabilities are that the flowers would be not so double, and might become single. The only suggestion I can make is to advise taking the offsets, plant each one singly in a thumb-pot, and pot them on as they require it, using good loam, to which has been added a third part of decayed manure, some leaf-mould, and sand. The plants should be grown in a well-ventilated garden frame.—J. D. E.

—These do occasionally revert back to the single form, but the backsliders have in my experience been few in the case of a good strain to start with.—E. H.

3619.—**Culture of Gloxinias.**—If the plants are well attended to and have the necessary situation they will flower in six months, but I fear yours are a little late to do that, and in consequence may take a month longer. As soon as they are large enough to handle prick them off into pans filled with peat and leaf-mould in equal parts, adding silver-sand liberally. Place the pans in a shady part of the plant stove, Cucumber or Melon-pit, where the temperature is not lower than 65 degs. by night and 75 degs. by day. When the plants have about four or six leaves place them in 3½-inch pots, the stronger may require pots an inch wider. Use a similar compost as before, except that one sixth part of dried cow or bone manure be added. Drain the pots freely as abundance of water is required at the roots when the growth is being freely made. A position fairly close to the glass, but in the shade in a temperature not lower than previously named, is best, and if the pots can stand on a moist bed of ashes or gravel so much the better. Here the plants may remain until they flower.—S. P.

—What do you mean by "changing leaf"? Is it that the "rough" or proper leaves are being formed? If so, they should be pricked off singly, 1 inch apart, in well-drained pans or boxes of sandy loam, peat, and leaf-mould, and still be kept warm, close, moist, and shaded. In about another month they will be ready for small (thumb) pots, and if when a little advanced they are shifted into 3½-inch or 4-inch sizes they will soon begin to show the flower-buds. It is quite possible to flower Gloxinias in six months from sowing the seed—that is to say, if the seed is sown in February the plants will begin flowering in August.—B. C. R.

—Gloxinias will require to be pushed on in a close pit to get them to bloom in six months, from seeds. If the seeds are sown early in February and kept continually growing in a warm house or pit, the greater part will flower in autumn.—E. H.

3604.—**Ericas after flowering.**—The free-growing winter-flowering Ericas should be pruned back more or less after flowering. In due time a new growth will break out, and when the young shoots are an inch or two long, shift into larger pots, if they require it, using the best brown fibrous peat, rammed in firmly. After potting, keep a little closer for a time in a pit or frame. The watering must at all times have careful attention. Signs of omission or

Basket of Achimenes.

holes around the sides, the plants can be put into them at regular distances apart, and all made complete in a very short time. When this is done they should be hung up in a bonce where they can get plenty of moisture and be syringed for a week or two to give them a start, after which, with a temperature varying between 60 degs. and 70 degs., they make rapid progress and soon become covered with bloom. It should be borne in mind that Achimenes are shade-loving plants, and, therefore, the situation chosen for them should be where the sun does not strike them during the heat of the day, otherwise the leaves become blistered, and the growth hard and stunted, which greatly detracts from their usually healthy appearance. With regard to

Soil, nothing answers better for Achimenes than a mixture consisting of about equal parts of loam and peat, used in a rough state, and to this should be added a good sprinkling of sharp silver sand, so as to render the whole porous. After May they will grow well in any ordinary

stages or on backshelves of greenhouses, providing the soil containing them does not catch drip, nor in any way becomes too wet and cold for their safety. New varieties are constantly being raised from seed, but the undermentioned are all good kinds and deserving of a place in any garden:—

ACHIMENES ADMIRATION, rose-colour, with light centre; A. Ambrose Verschaffelt, a fine white sort, with the centre marked with dark rays; A. Aurora, scarlet, with yellow eye, very large flowers; A. Firefly, deep-carmine, spotted with crimson, yellow eye; A. Ghiesbreghtii, a Mexican species, with scarlet and purple flowers; A. gloxiniflora (also a Mexican species), the flowers are white—a distinct and desirable plant; A. grandiflora (another Mexican species), a tall grower, the flowers of which are reddish-crimson; A. longiflora alba, large flowers, white, slightly marked in the centre; A. longiflora major, a very fine blue sort; A. Masterpiece, a stout-growing variety, with violet

commission with this class of plants are very often fatal. Whoever undertakes to look after them must study the condition of the plant by rapping the side of the pot. This is the best guide. More hard-wooded plants are ruined by careless watering than anything else. In July, when the growth is completed, set the plants on a cool ash-bed outside to ripen. House in September.—E. H.

The free-growing *Ericas*, of which *E. hymalis* may be taken as the type, should be pruned as soon as they have finished flowering. Cut the strong young wood back to within 2 inches or 3 inches of its base; the weaker growths need not be shortened much. The slow-growing species and garden varieties of the *E. tricolor* type need no pruning, except it may be to shorten any growth or growths that are likely to grow more freely than the others. When they have started to grow again after flowering, they may be repotted, using good fibrous brown peat of a sandy character. *Ericas* are easily grown, but are sometimes injured by neglect to water them. If the sandy peat becomes over-dry, it is rather difficult to moisten it throughout again, and the fine, hair-like roots are killed by over-dryness. *Ericas* also like no airy position when under glass, and cannot bear a forcing temperature. Even in winter the temperature of the greenhouse where they are kept should not be high. Enough artificial heat to keep out the frost is all that is required; a high temperature and a close atmosphere are sure to bring mildew. This parasite is troublesome, and should be destroyed as soon as observed by dusting with flowers of sulphur.—J. D. E.

3607.—Treatment of Palms.—The better class of Palms are hot-house plants, and are easily grown. They require liberal treatment—that is, good rich loam and decayed manure, and plenty of water when growing; but it is astonishing how they manage to grow and thrive in flower-pots, small for the size of the plants. They may be repotted at any time. I have frequently left them in small pots until the mass of roots split them in two: repot firmly, removing the compost well in.—J. D. E.

3633.—Which is the right boiler?—This is a difficult question to answer, as opinions vary as to which is the best boiler. I have my own views on this matter, which, if expressed here, might lead to the assumption that undue preference was given to a certain manufacturer. You appear to have sound views about the various forms of boilers now in use, and I gladly follow you when you give preference to a form that requires setting in brickwork, like the coil. The only objection I have to the coil is that they quickly burn out; but they are open to the same objection of which you complain of in other forms—of the waste of heat up the chimney. You will, however, have to bear with this. Next to the coil, I should prefer a flued saddle, as this form is the most economical with regard to the consumption of fuel of any that I am acquainted with when it is properly fixed, and a small size will be sufficient to heat 250 feet of 4-inch piping. Although the forms which you mention are cheap enough in the first place, you must bear in mind that the interior parts of the furnace quickly burn out. One of these forms of boilers, which cost me £4 when new, got so out of repair at the end of the second year that I had to lay out considerably over £1 to get it into working order again. Any hot-water engineer will fix a flued saddle and guarantee it to last for ten years without any further expense to you. If you compare this statement with the account of my experience of those forms that do not require setting in brickwork, you can quickly decide which will be the cheapest in the end, to say nothing about the worry of having to replace the worn-out parts in the independent forms.—J. C. C.

This is by no means an easy question to answer. There are so many different kinds of boilers, and all, or nearly all, have their good (and bad?) points. One of the most easily managed, satisfactory, and economical boilers I ever had to heat about this quantity of piping was a "Star" (upright independent cylindrical type, with waterway all round the fire). It seldom needed attending to more than twice a day—morning and evening—when the heat was cleared of ashes and slinkers, the upper lid of the boiler raised, and the draught regulated. There was

always a good fire in the morning, and the pipes as hot as at night, while, except in severe weather, it consumed very little over a bushel of coke in the twenty-four hours. It cost £5, and after nearly four years of steady work was still in good condition; but, as a rule, these boilers do not last more than five or six years. Those of a conical or slightly tapering form are the best, as the coke is not liable to "hang" in the hopper as in those of the cylindrical form. A plain saddle, properly set, would do the work well and economically, and last much longer; but the cost of the boiler, fittings, brickwork, &c., would amount to twice or thrice that of the foregoing. Coils are much cheaper than any other kind of boiler, but they are not particularly economical in working, and especially if not properly set and carefully fired, soon burn out. The cast-iron saddle, with waterway back and two side exits into flues, is an excellent boiler in every way, and with careful stoking will last a lifetime. I should choose either this or one of the "Star" type.—B. C. R.

THE KITCHEN GARDEN.

LATE CELERY.

The supplies of late Celery must soon be taken into consideration, and at this season of the year places such as old spent hot-beds are available for raising this crop. I am well aware that it has been advised in warm districts to sow on an open south border for the last crop, but I do

Celery "Sandringham Dwarf White."

not advise this, as I get better results by getting the seed up as quickly as possible after sowing. To do this, a moist, close place is essential, as in the open the seed-beds dry up quickly, and frequent supplies of water have to be given. If sown in a cold frame, it should be where the light can be removed as soon as the third leaf is formed, as it is necessary to get a short, sturdy growth. As soon as the seedlings appear above ground no time should be lost in

thinning to give the seedlings room to develop. When sown in this way it should be on a flat surface, as if sloping, the moisture, so necessary to the well-doing of the plants, escapes. Some advise sowing in heat, but as far as my experience goes for the late crop the less heat the better. A close place and enough moisture to cause germination are all that are necessary at the start, and there must be no lack of moisture as soon as the seedlings commence to form the rough or third leaf. I consider it one of the worst systems to sow these late crops in pans or boxes, as often through peas of work the seedlings get drawn and weakly, and frequently a month or six weeks is lost before growth starts. If grown as sturdily as possible, they never suffer from their shift when planted out. When sown thinly and plenty of room can be given, there is no necessity for transplanting the late lot, as if given plenty of room the seedlings can be lifted with a good ball and planted direct into their permanent quarters. I believe much of the success of the plants depends upon the treatment in the earlier stages and the amount of moisture. I find that seedlings lifted from the seed-bed, provided they have been

grown as hardy as possible with plenty of space, do much better than those raised in heat and transplanted. The Celery when planted as advised need not be so large as is often the case; indeed, it is often too large. When raised as above, there will be no flecking, no shading, and no loss of outside leaves. I grow two varieties for late work, and find them most suitable on our light soil. To give a supply through January and February I prefer Sandringham Dwarf White (here figured), and find it excellent; it remains good to the last; and to carry on the supply till May Standard-bearer is my favourite variety—indeed, I find no other remains good so long a time without flanking. It may be had good to the middle of May with little trouble. Some may object to it for cooking on account of its pink colour, but as April comes in there is very little pink left. It is equally useful as a vegetable as the white kinds. I do not grow the large Celeries for late use. I find them less useful, and after several years' experience of this variety I cannot fail to recommend it as the most useful I have grown. Celery, like other vegetables, differs in different soils, so that those who find a special variety succeed should not reject it for those they have not tried. The

earthing up of late Celery has much to do with its good keeping. If earthed up too early, growth is arrested and premature decay sets in. To get hardy Celery to resist severe weather, earthing-up must be delayed till the last moment. This allows the weather to harden the growth and there is never any shock, as the longer the earthing-up is deferred, weather permitting, the later the Celery will keep, and though the plants when grown on the surface may require a little soil to prevent the leaves going wide, earthing-up should be avoided as long as possible. I have also seen too much manure placed in the rows for late Celery. I do not think it is necessary, as it promotes a soft, succulent growth, often causing it to run. I prefer a moderate quantity, and to give two or three dressings of fish-manure during the growing season. The fish-manure prevents slugs doing injury when the soil is plowed to the plants. Salt is also good given in moderate quantities, placing it in the rows before watering. Plenty of water is necessary in dry seasons, and liquid-manure when in active growth is also beneficial. (1)

3603.—Forcing Rhubarb for market.—Rhubarb is very easy to force; it is only a question of artificial heat of some kind, and a good stock of strong roots of the early kinds for gathering first, and Victorin for later use. Every Rhubarb grower acts according to his convenience. There is no better place for forcing Rhubarb than in a roomy Mushroom-house. A friend who grows Cucumbers largely, fills one of his long houses with Rhubarb roots packed closely together, leaving a path down the centre for gathering and watering. There are many ways of forcing Rhubarb; everything depends upon circumstances and the means at disposal. A good deal of the forced Rhubarb comes from Yorkshire, and is forced by utilising the waste steam from the boilers in the factories.—E. H.

3614.—Dark spots on Tomato leaves.—There can be little doubt that your plants are affected with the Tomato disease (cladisporium), caused probably by shutting up the house closely at night, with too much moisture about. The best course is to dust the leaves of the plants (chiefly on the under-sides) with sulphur, to ventilate abundantly not only by day but to some extent at night also, unless very cold outside, and keep the atmosphere moderately dry, especially towards evening. This will probably get rid of the affection in time.—B. C. R.

The dark spots are fungus growths, and if not got rid of by a freer ventilation and a more buoyant condition of atmosphere inside they will spread until all the foliage is destroyed.—E. H.

Dressing Asparagus beds with fish-manure.—The old system of dressing with salt in damp, showery weather is not adopted so freely since the artificial manures have been so much used. The value of salt for the above is some coils is much greater than in others, but the time of applying it must be taken into consideration, as if wet clay land is dressed too soon, growth, instead of being assisted, is retarded. The best plan I have found is to dress the beds several times during the season of

cutting. For early dressing I have found nothing to equal fish-manure. It is an excellent fertilizer, and does not retard growth by keeping the beds in a cold, wet state. I have great faith in fish-manure, as I find it excellent for Celery, and equally good when applied to Spakale whilst making the summer growth. It is also reasonable in price. I do not advise a heavy dressing at first, but to dress lightly several times during the season, and in dry weather to wash it down to the roots by flooding with the hose. I need fish-manure largely for our permanent forced beds, and it is surprising the difference in growth when the beds are uncovered and a dressing of manure applied before the new permanent growth is made. Fish-manure, being very powerful, must be carefully applied. I have used guano and soot

Mercury (Good King Henry) as a vegetable.—This plant is not much grown in some districts, but in Lincolnshire it is in every cottager's garden. A few years ago I was ignorant as to its qualities as a vegetable. At this season when green vegetables are scarce it forms a welcome dish, and those who like Spinach will not object to it. This vegetable is useful on account of its hardiness, as it will live where Spinach is killed. It is not over fastidious as to soil, but is worth good cultivation, and may be sown on good land well manured, giving it a warm position. The cottager generally gives it a warm corner next the cottage facing south, and thus gets early growth. When highly cultivated the shoots may be had of a good size, and if these are earthed up in the early part of the year with decayed manure or leaf soil, they

HOUSE & WINDOW GARDENING.

UNTRAINED AZALEAS FOR TABLE DECORATION.

THE exceeding beauty of a naturally grown Azalea as a table plant when in flower is well shown in the annexed illustration. The question may reasonably be asked why, generally speaking, the Azalea, one of the most beautiful of all our greenhouse plants, is specially selected as a fitting victim for the mathematically accurate trainer to exercise his skill upon? True, the plant in question readily lends itself to this ill-treatment, and the beauty and profusion of its flowers in their season to some extent gloss over the unnatural form which the plant is made to assume, one that is, moreover, quite contrary

An untrained Azalea for table decoration.

mixed with salt, but prefer the fish-manure. Those who can utilize liquid manure from the cow-yard during the summer months will find it the best fertilizer, especially in hot, dry weather on raised beds in light soils.—G.

French Beans.—It is not safe to sow French Beans much before May 10, and then only a few should be sown. A part of a warm south border should be given up for the earliest sowing. Seeds may be forwarded in small pots or boxes if needed. The soil for French Beans must be in a highly fertile state, and also well pulverised. For the smaller growing varieties the rows should be 2 feet apart, and for the stronger growers 30 inches will not be any too far apart. The seeds must be sown thinly, or in double rows about 4 inches apart. The wisest course is to allow a few extra seeds to allow for thinning, especially for the earliest crop.—A.

are but little inferior to Asparagus, and may be served in the same way. The shoots must be used young, as the outside skin soon becomes hard. This if left must be removed from the older growth. The seed should be sown in April or May in rows 2 feet apart, thinning out the plants to 1 foot or more on good soil. Divide as soon as the shoots commence to grow.—W.

3548.—Tomatoes in a small house.—A good deal depends upon the kind of Tomato grown as regards setting early in the season. Perfection is not a good settor, but then if only two or three fruits set to a bunch the crop will be a fairly heavy one. Conference and Ham Green Favourite are good settlers, and the Old Red never fails.—E. H.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

to its nature. Azaleas do not naturally grow into perfectly formed pyramids or bushes so accurate in outline that they appear to have been clipped into shape with a pair of shears. On the contrary, their greatest beauty mainly consists in the tendency they have to form an irregular outline. All the training really requisite for even the largest plants of Azaleas is judicious stopping of the shoots when the plants are young, and a few well-placed stakes and ties to support the main branches when a more advanced period of their existence has been reached. Anyone taking up the culture of this delightful plant, which can be grown to perfection in a cool greenhouse, and when in flower be removed to the dwelling-house, for the first time, should bear these facts in mind, and by so doing a great amount of labour which would be much better devoted to other work in the

garden would be saved, and the result will not only give pleasure to the worker, but also to those who only see the fruit of his labour.

H. B.

3555.—**Palm-leaves dying.**—A frequent reason for the common complaint that the tips of Palm-leaves grown in rooms are apt to turn brown is that they are injured by being brushed against. A thoughtless servant will often take the plant off a table and push it against the wall or the furniture while she dusts, which naturally destroys the tips of the leaves. But if this is not the case, it may be that the brass bowl in which it stands is in laist. Surely the plant is not growing in a brass pot? If so, it must, of course, die for want of air to its roots, to say nothing of want of drainage; but probably "L. M. L." means that the earthenware pot is slipped into another of brass. If, however, this second cover be a tight fit, it would impede the air, and render the roots unhealthy, while it may retain water at the bottom which should run off. Palms need thorough drainage, and should never stand in water; they must not, of course, be ever drier-dry, but, on the other hand, should never be watered until the upper soil is dry (not moderately wet), then giving enough to run through the pot, but emptying the saucer an hour after watering. If the Palm is unhealthy, it will be well to examine its roots at once, as it may be repotted at this time of year; and after giving it a slight shift, with plenty of drainage (well arranged so that the water can pass off), and ramming down the new soil with a stout stick between the old ball of roots and the pot, the plant had better be put for two months or more into a hot-house or conservatory, where it will have a chance of starting new roots and throwing up healthy leaves. The compost needed for a Palm can be bought ready mixed in a small bag at the horticulturalists; this is a more economical plan than buying the separate necessary parts of it. Another good plan for an amateur is to take the plant in a nurseryman, and get him to pot it and plunge it in heat for a month or two, hardening it off gradually again before it is replaced in a room.—I. L. R.

The plants have possibly got into a thoroughly bad condition at the roots, or you give too much water, as unless the Palm has sun the soil does not get dry very quickly, but becomes sodden and unhealthy. If the roots are at fault turn the plant out of the pot, and this is a good season of the year for the work. The soil used should be good yellow fibry loam, mixed with a fair proportion of sharp silver-sand, or you may use fibry peat; but whatever is used must be made very firm, otherwise success will not come. Give the plant, if possible, a little heat after repotting, so as to get it well established again quickly, and take care not to overwater, otherwise it will soon die. During the summer months some shade is necessary to get the foliage of a fine deep-green colour, and a good supply of water is necessary.—C. T.

3628.—**Auriculas in pots.**—It would not do to place a number of offsets together in 5 inch pots in order to save trouble. Auriculas require a good deal of attention, and no one would be likely to succeed who begins to talk about saving trouble. All offsets should be removed as soon as ever they are ready to be taken off. Plant one, two, or three of them in thumb-pots, and pot them off again as required. The Auricula needs good rich soil in order to do it well. Good fibrous yellow loam three parts, one part decayed manure, and one part leaf-mould, is a good compost for them. The only way to get those shy of producing offsets to do so freely is to cut the plant over; it will break out freely from the crown.—J. D. E.

3009.—**Watering a garden.**—After the long spell of dry, lovely weather which we have had watering should either be very thorough or only those plants which seem to be suffering from lack of moisture should be watered with a spout—thoroughly drenched, in fact. Sprinkling only tends to weaken your plants, as it induces them to form their roots near the surface, instead of striking downwards. During the last two months I have watered nothing, unless it absolutely required it, and my plants look vigorous, and are remarkably so for the time of year.—A. G. BUTLER.

ALPINE AURICULAS.

MANY appear to think that the raising of Auriculas from seed is attended with some difficulty and a considerable amount of uncertainty, this erroneous impression doubtless taking its origin in the frequent failures arising from an imperfect appreciation of the character of this hardy flower. A method frequently followed is that of sowing in warmth in early spring. There are two objections to this method, one being that the germinating powers of Auricula seeds decrease at a rapid rate when kept out of the soil; the other that the Auricula is naturally very impatient of the application of artificial warmth. So far from artificial heat conducing to free and quick germination, I believe the contrary to be the case with this hardy flower at least. The important point is to employ new seed, and for this reason I would advise those who may intend to raise a stock of young plants to order the seed when the natural blooming season of the Auricula arrives, specially stipulating that it shall be fresh gathered and to be sown as soon as ripe. Seed purchased in spring has, of course, passed some months out of the ground, and although it may be quite good, its germinating powers are so sluggish that one can expect but a sprinkling of plants when sown. These should be carefully taken out with as little disturbance of the soil as possible, for it must not be concluded that the seeds that have not germinated are bad; they will in all probability come up later on. The best thing to do is to plunge the pots in a cold frame, covering the soil with Moss and just looking to them now and then during the summer, so that the soil does not get dry. In this way most of the seeds will come up in autumn or during the winter, as that by the following March every good seed will have made a plant. It has always appeared to me that Auriculas germinate most freely at a temperature but little above freezing. It is probable that in alpine regions they germinate under their snow covering, and a German grower advises as a certain way of getting the seeds to grow freely that they be sown in winter, covering the soil with snow, which is to be allowed to remain until it melts. Some years ago when commencing the culture of these hardy Auriculas there happened to be a good deal written respecting the best way of raising them from seed. Various plans were recommended, most of which I tried with more or less success, but in no single instance did I succeed in getting the whole of the seeds to germinate, and there was always a difference of several weeks in the appearance of the first and last seedling. Eventually it occurred to me that I would try sowing late in autumn, thinking that if the seeds remained in the soil through the winter they would come up earlier in the spring, and perhaps more regularly. They were sown in boxes in the ordinary way, but I allowed space for a covering of Moss, a piece of glass being put on to keep off drip. They were plunged to the rims in a cold frame, remaining undisturbed until the end of the year, when, happening to look to them, I found young plants coming up; by the end of January they had quite covered one side. Every seed appeared to have germinated. The following year I adopted the same plan, and with identical results. It is, therefore, very evident that in the case of the Auricula, artificial heat is not likely to favourably influence germination.

AUTUMN SOWING is, however, preferable for the reasons above given, and the sooner the seeds are committed to the soil after maturing the better. Requiring a considerable number of plants, I dispense with pens or boxes and sow in a frame where the young seedlings can remain through the winter. The soil is well watered before sowing, the seeds being very thinly covered and kept quite dark until they come up. I find that in this way it is no more difficult to raise Auriculas than the common Blue Lobelia. With the shelter of a frame the young plants remain quite fresh and green all through the winter, presenting quite a different appearance from older specimens at that time of year. In hot summer weather they should be kept well watered with an occasional dose of liquid manure, and by the end of the autumn they will make nice little specimens large enough to yield a moderate amount of bloom. Even when sown in a cold frame, the seeds will, whether

of the alpine or show varieties, this method is far preferable to growing the young seedlings along in pots, as they give much less trouble and make double the growth. If any are required to bloom in pots, these can be selected and marked when in bloom for potting up the following August. The best position for Auriculas is undoubtedly a north border, but it must not be overshadowed by trees or high buildings. A certain amount of sunshine is, I am convinced, beneficial, and this the plants will get in early morning and towards the close of the afternoon in a north aspect, if there is no obstacle to the admission of the sun's rays. I grew my plants fully exposed to the sun, and they bloom remarkably well; but I find that if we get hot sunshine with a dry condition of the soil the blooms quickly lose their freshness. They last double the time where they escape the effects of the midday sun and parching winds that so frequently accompany it in spring. Hot sun, frosts, and heavy rains are the great enemies to Auriculas in their blooming season, and it must be admitted that they seldom escape the effects of these adverse climatal conditions. Heavy rains come mostly from the south and west, so that plants in a north or east position are less likely to have their blooms spoiled. I have not found Auriculas very capricious as regards soil, but they are impatient of stagnant moisture at the root during the winter months. Where the soil is naturally heavy it is better to plant somewhat above the ordinary ground level, and some river sand or light material of any kind should be added. The best results will, of course, be obtained when good loam is used. In light porous soils they are apt to have their blooming-time considerably shortened by drought, and if some good holding loam cannot be added, the surface should be mulched with Coconut-fibre or something similar. As regards transplanting, I am in favour of doing this early in autumn, as then the soil gets well settled round the roots by winter. In a general way it is advisable to transplant Auriculas every third year, as they have a tendency to push their crowns above the soil, in time forming naked stems several inches long, and the ground becomes hard and spongy through heavy rainfall. If this is not done many of the plants will die out; whereas with periodical transplanting they will yearly increase in size and effectiveness. As to the ability of Auriculas to withstand the vicissitudes of our winters, it appears to me that if enjoying suitable conditions as regards position and soil, frost alone makes no impression on them. It is only in waterlogged soil and when the crowns do not properly mature that they are likely to perish. J.

BULBS AFTER FLOWERING.

BULBS are probably treated about the worst of any family of plants; not only are they kept out of the soil for weeks, and even months, after they ought to be rooting, and gathering strength for flowering, but directly the blossoms fade we hear people talking of digging them up again at this time of year. I am constantly receiving queries as to whether the bulbs that begin to look seedy had not better be dug up, dried, and stored away. But the middle of April is far too soon to lift even the very earliest flowering bulbs, and the middle of May is plenty soon enough; in fact, where it is possible I like to let the foliage get quite sere and yellow before lifting is done, for as long as any life is left in the foliage, it is doing some useful work for the bulbs, and, as a rule, tender bedding plants that usually follow bulbs cannot safely be planted out until the middle of May. Now, if the bulbs are expected to last good for any length of time no pains should be spared to get the bulbs carefully ripened off in the soil as long as possible; but if any vitality remains in the foliage when it is imperative that they must be lifted, do it in the following manner—viz. take a steel fork and, digging them up carefully with all the roots that can be got, lay them in boxes packed closely together with a little soil worked among the bulbs, so that they may derive all the benefit possible from the foliage, and after they are perfectly a rest divest them of the old foliage and store them away in a cool, dry place, until the time for planting again comes round. J. G. HANTS.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers to be inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be written and sent to the Editor of GARDENING, 27, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents would bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communications.

Answers (which, with the exception of those answers which will be found in the different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that general answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents refer to articles inserted in GARDENING should mention the number in which they appeared.

3657.—Celaena crotia. —Will someone kindly tell me where to buy the seed of this flower?—R. S.

3658.—Dandelion on a tennis-lawn.—Will anyone kindly tell me how to destroy Dandelions on a tennis-lawn?—E. B. H.

3659.—A cleanly plant stimulant.—Will someone please to recommend a cleanly good stimulant for lady's use for herbaceous plants, Fuchsia, &c.?—SCOTIA.

3660.—Treatment of an Oleander.—I have a young Oleander about 8 inches high. Should the top of the shoot be pinched out, and what soil is best for it?—L. T.

3661.—Wire-netting for Peas.—Would wire-netting do for Peas instead of Pea rods with large stakes driven in the ground for such a Pea as Duke of Albany?—BAYLY.

3662.—Keeping Apples.—Will anyone kindly tell me how I can keep Scarlet Nonpareil Apples until next August? Those I have are good sound fruit, and I want to keep them so.—H. C.

3663.—Bottling Green Peas.—Will anyone kindly give me a recipe for bottling Green Peas and Scarlet Runner Beans, so as to keep them in their green state for use in water?—LINDEN.

3664.—Best Melon and Vegetable Marrow.—Will anyone kindly tell me the best kind of Melon and Vegetable Marrow to grow in open ground and all particulars of rearing the same?—H. W. H.

3665.—Chrysanthemum for show.—Will "E. M." kindly oblige with remainder of culture of Chrysanthemum for show, as he kindly promised in GARDENING issue of Dec. 3rd, 1892?—W. E. ANDERSON.

3666.—Melon "Little Heath."—I am raising some "Little Heath" Melons in a small frame hot-bed. Will "J. C. C." give me a few plain, practical hints as to the treatment of the plants when raised?—C. A. M.

3667.—Malmaison Carnations.—Would someone kindly tell me the best way of growing the above? I had a beautiful strong plant doing well all the winter and full of buds in one day; it began to droop, and within the week seemed quite dead.—A. B.

3668.—Wireworms in a flower-garden.—I am troubled with a great number of wireworms in my flower-garden which eat the plants off just below the surface of the ground. Will anyone kindly tell me of something that will destroy them?—DOLMAN.

3669.—Stopping a Vine.—Will someone please tell me when to stop my Vine? It is now in bud. Should the shoots be stopped and pruned before or after it has flowered? Is it too late to use stimulants to the root, which is outside the house?—L. T.

3670.—Narcissus not flowering.—What would be the reason of a double Narcissus not flowering? They make lots of dead heads, but few flowers. Some years ago I took them all up and replanted them; they were too thick, but have never had so many flowers since.—J. WHEELER.

3671.—Good King Henry and Salsify.—I have just sowed some seed of "Mercury" or Good King Henry and I find I have to leave this place in autumn. Will these plants be of any use to take with me? Also I sowed a bed of Salsify, and wish to know if the roots can be dug and stored for winter use?—STAMP.

3672.—Zygopetalum Mackay.—I have just bought two nice plants of Zygopetalum Mackay. Will someone kindly give me some hints as to growing these? Should they be in sun or shade, and when do they flower and what colour? Some of the bulbs have no growth. Will they make no more now?—JUDY.

3673.—Lily of the Valley in a bed.—I have a large bed of Lily of the Valley, very thick indeed; have not been thinned for fifteen years. I manure every winter. Is it the correct thing to thin them, and how? They are in compact mass, and I have to examine closely to find the flowers.—J. WHEELER.

3674.—Unhealthy Larches.—I have a number of young Larches which seem suffering from blight or dieback. The stems are covered with fine white spots, the leaves blacken and fall off, and eventually die. Is there any remedy for this? Would washing with paraffin or anything else cure it? I have already lost 12 to 20 trees.—A. B.

3675.—Bleak Hamburg Vine leaves withering.—Will someone kindly say what caused my Vine-leaves to wither or go brown? They were planted in an inside border (see last issue). They are now very morning about 9 o'clock. The heat often rises

to more than 90 degrees, with full air on. Cold draughts often blow through the lights, which, I think, cannot be avoided. The floor and staging are damped several times on hot days, and wall two or three times. The house is closed about 8.30 p.m. There is no fire-heat, except a little in the evening, and I might have mentioned the house is facing south and is full of pot-plants. I shall feel thankful to any person who will say how to prevent this mischief, and give a few hints on the future management?—NOVICA.

3676.—Auriculas.—I have some beautiful blooms in the open air, and am anxious to take cuttings to rear in pots for next spring. Will these survive if broken off without distinct roots and potted as cuttings? If so, should they be kept in pots throughout, or when well-rooted planted out and re-potted in the autumn?—BERRILL.

3677.—Pansies, &c. from seed.—It is better to raise Pansies, Marguerites, Sweet Williams, Wallflowers, and Forget-me-nots from seed each year, or to keep the old plants for two or three seasons? If the former, what is the best time to sow, and is a frame better than the open ground to sow in? My soil is a good dry one.—AMATURUS.

3678.—Virginal Creeper and Pyrus japonica.—Can I raise Virginal Creeper and Pyrus japonica easily from cuttings, and would they strike to a frame now? Would it be better to take them now or later, and should I take old wood or this season's shoots? How long would the Pyrus be before it would flower from cuttings 6 inches long?—AMATURUS.

3679.—Oologyne cristata.—Is it necessary to re-pot Oologyne cristata, Chatsworth variety, every year? My plants have just borne flower-spikes, which being faded I cut off, and immediately more spikes have begun to grow from other and same buds. Are these more flowers or new bulb growth? I did not know. I imagine if flowers, re-potting would be injurious?—JUDY.

3680.—Tap-water.—Will tap-water obtained from the waterworks, containing a quantity of soda, injure plants in the greenhouse that are watered with it? It also left injurious to plants out of the greenhouse, and if so what can I do to make it fit for use for either purposes or for syringing? I should be glad of an answer from any person who has had to deal with such water.—J. R.

3681.—A plague of ostarpillars.—Should be glad to know what is the best remedy for a plague of ostarpillars? The Gooseberry-trees are fast being cleared of all their leaves, and the Red Currants similarly, but it seems the Gooseberry foliage is the favourite. I have tried paraffin and water (two glass and half to gallon), also Jay's Disinfectant, but they are as active as ever.—J. WHEELER.

3682.—Sewage in the garden.—I have a pump in my garden connected with a tank to which all the sewage of a large house is conducted, together with drainage water, by a pipe about 100 yards long. My gardener doubts whether the liquid pumped up is fit for use as liquid-manure in the garden, and as I am not well up in the subject myself I shall be much obliged if you will trouble me with any information about it.—G. J. JOURNAL.

3683.—Management of a Vine in a pot.—Would "J. C. C." kindly give me a little information respecting the management of a Grape-Vine, in a 16-inch pot? It has two rods, one of them is 3 feet long, the other 6 feet long. The longest rod has now ten bunches showing. Should I pinch back at two leaves beyond the bunch? Also should I pinch back all shoots on both rods? How many bunches may I leave on? It is a white Grape, but I do not know the name of it. I intend to plant the Vine next year in an inside border in the greenhouse. The border is 12 feet long by 8 feet wide, the bottom is broken hillocks and stones, with about 1 foot of soil on the top of drainage. How much more depth shall I require?—FURZE.

3684.—An allotment question.—I have an allotment of 10 perches, which, of a former paying him 6d. per perch, with others, which I took of his agent last summer, it being the half of 20 perches held by a man who does not cultivate his 10 perches, which, of course, has got very foul, and at the present time is overrun with Collifoot, Dandelions, Thistles, &c., which are flowering and seeding my ground. What power have I to stop it at once? I have made an offer to the agent—it will give me immediate possession I will pay the rent from March 25th last—when he refuses, but promised to get the ground dug up last summer, but never set about it. Can I force him to dig the ground up at once? If so, how should I proceed in the matter? I may add I am a poor working man, and cannot afford to consult a collector in the matter.—FOUR LANE.

3685.—Questions for a Surrey garden.—I have got the Apple and Cherry-trees kindly recommended in GARDENING (and much ado I have to keep them alive in this terrible drought). One thing puzzles me—the Cherries are standards about 8 feet high below the graft, then comes a bunch of about four horizontal at the foot of some long straight shoots, each 18 inches or 2 feet long. Ought these to be pruned back, and when and how many eyes ought there to be cut off? The Apple-trees are in much the same condition. Can I make a Mushroom-bed now in the open air without a frame? How ought I to cut back Roses this year for pegging down next year? Has anyone had bushes little over 1 foot high of Reine Marie Henriette and Charles Lefebvre. I ought the shoots, when they grow to be pegged so as to touch the ground, or how high? I planted in November last a hedge of Thuja Lobbi on the top of a newly made bank 3 feet high by 8 feet wide. It looks quite brown and dead. Would it be any good to cover the roots with Cocoa-nut-fibre? It is difficult to water sufficiently as no hose can be used. The soil of the bank is good loamy turf. How can I save the trees?—IGNORAMUS.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3686.—Spanish Iris (W.).—Although late it is best to plant your bulbs of this Iris at once.

3687.—Syringing greenhouses (B.).—This question is purely local one; we cannot advise you to experiment in your own neighbourhood.

3688.—Rhododendron fragrantissimum (Bristonia).—We should say you can procure this Rhododendron at any nursery where their culture is made a speciality of.

3689.—Grass edging for borders (Amateur).—The best way to form Grass edgings to your flower-borders will be to procure some good turf, and lay down as for lawn making.

3690.—Australian seeds (Antipodes).—The plants that you may raise from the Australian seeds sent you, we should say, would succeed in the temperature of an ordinary greenhouse.

3691.—Cyperidium barbatum J. Leigh.—This plant differs from C. insignis, inasmuch as it does not care for loam; but it should be grown in well drained pots, in peat-fibre and Sphagnum Moss.—M. R.

3692.—Blanching Celery (Amateur).—This term applied to Celery simply means to whiten the leaves of the plant by drawing the earth up around them, and thus, being in darkness, they become white in colour.

3693.—Building a greenhouse (B. S.).—The better way would be to consult a respectable greenhouse builder, who would, on doubt, give you satisfaction. We cannot give plans or estimates for such structures.

3694.—Unhealthy Bay-tree (Laurus).—The best plan would be to prune the tree back rather hard, and mulch the roots well with manure, and give good soakings of water in dry weather. This treatment might restore it to health.

3695.—Olema-leaves turning yellow (H.).—The probability is that you are right as to the cause of the Olema-leaves turning yellow—viz., want of water at the root. Give it a thorough soaking, and then mulch with short decayed manure.

3696.—Evergreen Japanese Aralia (Aralia Sieboldii) (Scotia).—The evergreen Japanese Aralia is a worthy spreading plant with a single stem. This is the best and most effective way of growing—all it needs to keep it bushy is abundance of light and air.

3697.—Heat ofinery (B.).—The temperature in the newly-plantedinery may range from 85 degs. at night to 85 degs. and 90 degs. in the day time when the sun is shining, and make all possible use of the sun's rays by closing your house early in the afternoon.

3698.—Budding Roses (J. B. D.).—Roses can be budded with success on the suckers that spring off from old stocks; but re-planting your garden with young Rose trees on their own roots, or worked on the seedling Brier stock, we should imagine, would be your best plan.

3699.—Creeper to cover a roadway (Archway).—Plant a strong-growing Clematis to run over and cover the archway you wish to hide. There are now many varieties, and the colour of the flowers is very varied. They can be obtained easily from most nurseries.

3700.—Vines bleeding (W. H.).—It is difficult to stop the bleeding of Vines if, in any case, a branch is broken off, when the sap is in active motion—in fact, it is almost impossible to arrest it's flow. Try an application to the wounded part of the ordinary painter's knotting.

3701.—Planting out Calceolarias (Bedder).—These are very hardy plants, and may, generally speaking, be placed in the open ground about this time with safety. In exceptionally cold localities it would perhaps be wiser for you to wait for a week longer before planting out.

3702.—Camellias and Azaleas in unheated house (Streatham).—Let the plants complete their growth and set their flower-buds in the heated house, and when that is the case, you can transfer them to the unheated one, and give abundance of air during the summer season.

3703.—Diseased Strawberry (Fruit Grower).—If you will let us know the name of the Strawberry-plant sent, we may be able to tell you the cause of their dying off so. Are they Sir C. Napier or British Queen. These are the sometimes very capricious as to soil and situation.

3704.—Marooned Niel Rose-leaves falling off (Leicester).—It is evident the Rose is infested with red-spider. You probably kept the house too hot and dry, and maybe do not water sufficiently at the root. Syringe freely, and avoid high temperature. This may help you.

3705.—Dracena dying (Bessie).—Probably the cause of the Dracena dying is the low temperature of the room in which you have grown it, and the exposure to the cold draught of an open window. Plants of nearly all kinds are impatient of draughty places, and none more so than the Dracena.

3706.—Raspberry canes (C. P.).—The young suckers that are now springing up from the roots of the old Raspberry-canoe may be allowed to remain where they are now growing until they have completed and ripened their wood in this autumn, when they can be transplanted as you desire.

3707.—Mnlobing fruit-trees (Evesham).—Allow the mulch over the roots of the fruit-trees to remain throughout the summer, as then is the time of its greatest value, its main use being to prevent evaporation, and thus the trees do not suffer so much from drought, and their general health is much better.

3708.—Cyperidium ineigne (J. Leigh).—This species is best grown in pots, which, however, should be well drained. It is a plant which is not very particular to soil, but I like to use peat-fibre and chopped Sphagnum, mixed with some nice yellow fibrous loam, from which most of the soil has been shaken.—M. R.

3709.—Syringing Rose under glass (Rose Amateur).—Syringing night and morning during the growing season, or they will speedily become infested with insects and lose their foliage. If done with care it will soon injure the Rose, and then the best use for the purpose (always, if possible) clean, tepid soft water.

3710.—Hiding soil in a garden (Suburban).—If the soil is that of the flower-bed, then in that case you cannot do better than use Cocoa-nut-fibre refuse spread over the bed; but if it is the ground used for the culture of Vegetables or fruit-trees, then the only allowable plan would be to use a mulching of decayed manure.

3711.—Protecting Pear-trees in bloom (Pawson).—It is a good plan to use protection for the blossoms of your dwarf figs bushes against frost, and it can be easily done by having a light framework of wood or iron placed over them, and canvas coverings attached thereto to let down at night and to roll up in the daytime.

3712.—Vines losing their leaves (Friedwink).—Perhaps the Vines have become over-dry at the root some time during their season of growth—that would cause them to lose their lower leaves; or the temperature of the house in which they are growing has been allowed to fall too low. Vines delight in abundance of heat, light, and moisture.

3713.—How to use guano (Mauve).—The best way of using guano for pot plants is to give it as a liquid manure, adding a thumb-potful of it to about 4 gallons of water. Let the mixture settle, and use, in a clear state, about two or three times a week. You will find this a better plan than sprinkling the guano on the surface of the soil in a dry state.

3714.—Ceanothus turning canker (G. Hudson).—I should think that they must have been over-watered before they could rot properly, and I do not like them to be grown under Cucumbers. Give them more light, see that they are watered carefully, and that they are well drained. There is time enough for them to recover and to make good hulbs before autumn.—M. B.

3715.—Propagating Hydrangea (Propagator).—The best time in the whole year to propagate Hydrangea is the month of August, as by that time the growth has become firm and mature, the cuttings can be inserted singly in small pots in sandy soil, and if kept close in a warm frame for a time, they will soon take root, and can then be potted off as desired, using, if available, a rather heavy loamy soil for them.

3716.—Pinks, common Pansies, and Arabis (Plant Lover).—Pinks are best propagated in July, using strong shoots which will strike freely in light, sandy soil under a handlight in a shady position. Common Pansies are easily increased by division of the old roots in August and September, and they will thrive well in any shady, cold frame, and when rooted plant out in beds. Arabis is increased by the root cuttings, and by division of the roots and replanting in autumn or spring.

3717.—Dendrobium noble (J. Leigh).—Well, you have asked me a question about pruning this plant, and I do not much believe in the process, but you may safely cut away the hulbs that have flowered, because as this plant blooms naturally upon the two-year-old hulbs, you will not injure them in any way. How it is I do not know, but in the case of pruned plants that I have seen, they have flowered upon the last made hulbs.—M. B.

3718.—Cologne Maesangenna.—G. S. W. sends me two flowers, saying he has a plant with five spikes, and the smallest number of flowers upon either spike is twenty-three and the most twenty-seven, and speaks of it being beautiful. I have no doubt but it is, and the variety too is very good. This is one of the fine plants we have to thank Mr. Sander for; I do not know its native country, but it does best when grown in strong heat and moisture.—M. B.

3719.—Odontoglossum maculatum (James Elliott).—The flowers seem to appear to have been eaten by a beetle or some small snail. I should think my friend neglects the examination of his plants after dark, and thus these noxious pests have an undisturbed possession. During their busy feeding-time, you should go over the plants by the light of a candle some time about ten o'clock, when you may catch them at their depredations, and you will by this mean rid yourself of them.—M. B.

3720.—Cologne fasciata (J. Bierman).—This is the species you send, I opened it in the dark, and the odour was simply detestable. I never before was so taken aback with this species. It is a fine, strong spike, and you should grow it in a hanging-basket above the line of vision. In such a position the creamy-white flowers, marked with reddish-brown and yellow, will have a very pretty effect, and their odoriferous perfume will not have any effect in the house. It likes the East Indian house to grow in, but it may be well kept in the cool end of the Cattleya house during the resting season, at which time it should not be kept quite dry.—M. B.

3721.—Vanda Kimballiana (M. G. W.).—This is really a beautiful plant; my enquirer says, "he thought it was like a Vanda, but he finds it is not, for which he is very thankful." Well, if you have a plant that is well established, you will see no affinity to the Vanda you name, for the leaves, although rounded below, have a deep channel in front, and these are of a very deep green hue. Then it is a very free bloomer, having from six to seven or eight flowers upon a spike, each flower measuring about 2 inches across, the sepals and petals being pure white. The large middle lobe of the lip being rich purple, having some spots and markings of red and yellow on the side lobes. We all know, beside these beauties, it is a plant that will grow with the Odontoglossums, only requiring a more sunny position in the house, and in such a position I see the plants doing better than I have yet seen it in Mr. Lowe's Nursery at Clapton, who were the importers of this plant, through my esteemed friend, Mr. Boxall. It should be planted in sweet Sphagnum only.—M. B.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Name of plants.—E. J.—Dendrobium superbum.—William Parsons.—1, Gonoloparis scolopandroides; 2, Adiantum tenerum; 3, Pteris Kingiana; 4, Chelidonium alabamense.—S. J. B.—All forms of Dendrobium noble, but not a good flower amongst them.—N. P.—Aloha quinata.—G. G. Wells.—We do not recognize the hulbs; perhaps they are not yet strong enough to flower.—H. W. Trenchard.—1, Juncus-like Epimedium; 2, H. D.—Habrothamnus ciliatus.—Dick.—H. C. (Prunus Padut).—J. C. A.—Snowdrops (Hakel tetrapetala).—L. Warrall.—Cristatulum nudum.—C. L. Butler.—The Fern is apparently a Lastrea species,

but send again a fertile frond.—Robt. Greening.—Dog (Cornus Ma.).—Alderson.—Specimens sent were rotten from being packed in wet moss.

Names of fruit.—Ardmore.—The Apples were duly received and sent to an expert to name, but they were too much shrivelled to identify.

TO CORRESPONDENTS.

Amaturus.—Certainly it will be a good plan to shade the frame used for raising seeds in during the heat of the day.—Amateur Carnation Grower.—You can name the seedling Carnations as you desire, and there is no formality to go through, the matter being an entirely personal one.

Miss Dayrell.—Apply to Mr. A. G. Butler, The Lilies, 124, Beckenham-road, Beckenham.—Amateur, East D.—We know of no book that will help you so much as reading GARDENING regularly and attentively; any queries sent shall receive prompt attention.—C. E. W., Constant Reader.—Springs the Peaches freely with Tobacco and soapy-water and give plenty of water to the roots. Dress over the Gooseberries with Hellebore-powder; mind, the latter is poisonous.—J. Keenan.—A fine flower of Rhododendron Nuttall. If you have given the plant any special treatment we should be glad of a note from you on the matter.—East Kent.—We know nothing of the book you name.

POULTRY & RABBITS.

3423.—Chickens dying.—Laburnum seeds are usually looked upon as poisonous, and if "S. R. G." has any doubts about the matter he should arrange to keep the birds out of reach of the seeds. It is quite possible that the chicks referred to in the query were poisoned; still, it is not absolutely certain that this was the case, for the symptoms described are not unlike those which would be apparent in the case of chicks suffering from pneumonia or inflammation of the lungs. The weather too might have affected them, as the nights and early mornings have been cold.—DOULTING.

3454.—Pullet continuing to lay miniature eggs.—"Pullet" can do nothing to mend matters. The bird in question is probably imperfectly formed, and the best way to deal with her is to kill her at once. It may be taken as a good rule to follow, that whenever there is any defect in the eggs regularly laid by a hen, Duck, or Goose, it is more economical to get rid of the bird than to doctor her, since no improvement can be expected until egg production has been temporarily suspended, so that the egg-organs may receive a rest; and it frequently happens when the bird begins to lay again that matters are as bad as ever. The fact is, the egg-organs cannot be interfered with to any extent, and it is wiser in the end to leave them alone.—DOULTING.

BIRDS.

3722.—Zebra Finches.—I should be indebted to "Mr. A. G. Butler" or any other reader interested in foreign birds, if he or they could assist me in the following case. I have a pair of the above birds which I put up for breeding last year, but without any result. The hen, however, laid continuously throughout the summer, but unfortunately the eggs which she laid were broken by the cock before any succeeding ones were laid. I do not, however, think the cock did it wilfully and intentionally, but merely out of curiosity, as he was very attentive to the hen, and was not at all spiteful. As "Mr. Butler" undoubtedly knows, it is the habit of these birds to sleep in the nest. This, I think, in some measure accounts for the breaking of the eggs. I separated the birds in October. Some naturalists, I believe, advocate that the eggs should be removed from the nest as soon as they are laid. I accordingly abided by this, but before another egg was laid the egg had taken out dried up. I was advised that I ought to separate the birds when the first egg had been laid, but I thought perhaps if I did so the hen would perhaps lay no more, or if she did the eggs would be unferile. Usually I may mention that I give the birds the best possible attention. Their staple food consists of Canary and Millet in about equal proportions. In addition to this they often have a good supply of Hyde's gravel, which is rich in lime. This, I believe, keeps the birds in health, and guards against egg-binding. They also daily have a plentiful supply of Groundsel, Chickweed, Watercress, &c., but I notice they no seem to care much for it. I sometimes give them a little pulverized oyster-shell which, I believe, has the same properties as Hyde's sand. Fresh water they get every day. Occasionally I give the birds a bath, but they do not make much use of it. I shall be glad if "Mr. Butler" could give me a remedy for the above, and I should esteem any hints on the general management? Could he inform me how long the eggs should retain their vitality and at what intervals they should be laid? I thank him in anticipation.—HARVEY M. BARING.

3493.—Bullfinch after moulting.—Caged Bullfinches are always more susceptible than other wild British birds, and very few attain a respectable age. Even in a large aviary I have rarely found them live for more than two or three years. When moulting, like all Finches, they should be supplied with nourishing food, and cattle-fish bone should never be banished.

Bathe the bird's legs in hot water (about 120 degrees or comfortable to the hand), then dry carefully with a piece of flannel, and stand the cage near the fire with a covering over it to keep off the glare. In about half an hour move it away from the fire, let two drops of salad-oil drop on the surface of the drinking water, and give the bird a little pan of egg (hard-boiled) for a few days. The day after its bath and every day for a week put ten drops of Pariah's Food into the drinking water, and stir it until thoroughly mixed. If this treatment does not cure the bird, I am afraid its case is hopeless.—A. G. BUTLER.

"Gardening Illustrated" Monthly Parts.

Price 6d.; post free, 8d. The Garden Monthly Parts.—This journal is published weekly, but only monthly Parts. In this form the coloured plates are best preserved, and to be most useful for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 8d. Complete sets of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £50 12s.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d. London: 37, Southampton-street, Strand, W.C.

DOUBLE IVY-LEAF GERANIUMS.—Not so old as 20 years ago, but the best Continental productions. Every shade of colour, resembling Rose. 13 distinct, named, well rooted, 3s.; 6 ditto, 1s. 9d. free.—JAMES BATEMAN, Warrington, near Hastings.

CHOICE ZONAL GERANIUMS.—Dble. and single, all correctly named. Nothing can give greater beauty in a greenhouse than these. Well-rooted plants, 3s. doz.; 6, 1s. 9d.—JAMES BATEMAN, Warrington, Hastings.

LOBELIA Imperator William from cuttings, 3s. 100 Geranium F. (F. var.) dbl. crimson, 1s. doz.; 12s. 100. Abutilon, named, distinct, 1s. for 1s. Colons. In showy varieties, 2s. 6d. doz.—JAMES BATEMAN, Warrington, Hastings.

FUCHSIAS.—Nice young plants for growing into specimens. Read the names: Beauty of Cleveland, Purple Finesis, Mrs. E. G. Hill, Nancy, Moleworts, Delight, Ernest Gam, Topper, Mrs. A. Huggatt, Gustave Doré, Beauty of West Kent, Mr. F. Bright, Lady Heston, Harry Fry, Duchess of Edinburgh, Antelope, Eschomberg, Olympia, and a host of others equally good. 3s. doz.; 6, 1s. 3d. free.—JAMES BATEMAN, Warrington, Hastings.

120 CHOICE Bedding Plants, carriage paid, for 5s.—This Collection, offered for the eighth season, grows annually in public favor, and is unapproached in value and charming variety by any other offered.—12s. 25 each Geraniums (assorted) and dark blue Lobelia—10 each Verbena, grand striped Fuchsia, lotus, &c. (Chrysanthemums, best Heliochrome, 5 each Yellow Calceolarias, and scented Musk, 4 Marguerites. Every plant well rooted and hardened; half Collection, 3s. Any reasonable variation given and claimed in case of need. Anters, Phlox, and Tom-cats, should be the finest quality, are on sale, and may be substituted for any of above, or at 2s. 100.—JAMES BATEMAN, Warrington, Hastings.

NEW GIANT IRISH ANEMONES (St. Bridget), immense double blooms, in brilliant and infinitely varied colours; 2s. 1s. 9d.—J. CORNHILL, Byfleet, Surrey.

NEW HYBRID COLUMBINES, in many beautiful shades, 2s. 1s. 9d.; Perennial Iceland Poppies, in brilliant colours, 2s. 1s. 9d.—J. CORNHILL, Byfleet, Surrey.

RED JAPAN ANEMONE.—Finest and brightest of autumn flowers, 4s. 1s. 9d.—J. CORNHILL, Byfleet, Surrey.

NEW DOUBLE CORNFLOWERS.—Charming rosettes of blue, pink, white, purple, and many new shades, 2s. 1s. 9d.—CORNHILL, Byfleet.

GIANT TRIMARDEAU PANSIES.—Immense blooms, largest in cultivation, fine in colour, 2s. 1s. 9d.—J. CORNHILL, Byfleet, Surrey.

CHRISTMAS ROSES.—Not imported roots that die, but well-rooted, home-grown, 5s. 2s. 9d.; 12s. J. CORNHILL, Byfleet.

HERBACEOUS (spotted) Calceolarias.—Strong, stout, healthy plants. Kelway's First Prize strain, 2s. 6d. doz.; 16s. 100, carriage paid.—H. BLANDFORD, The Dorset Nurseries, Blandford.

TELEGRAPH CUCUMBER (Walter's Be-lotted).—The hardest and most prolific from cucumber grown. Fluctuates in size, contains 10 or 12, 1s. 6d.; 3 for 2s., post free.—ALFRED A. WALTERS, Florist, Bath.

BEAUTIFUL HARDY CLIMBER.—Amor-ica Belland, large pink blossoms, grows 20 feet in season; 4 good roots, 1s. free. Now is the time to plant.—BROUGHTON, Weston, Maidstone.

100 PACKETS named flower seeds (annual and perennial), 10s. 1s. 3d.—E. BIRKETT, 105, Westgate, Bury.

SWEET PEAS.—Twelve packets newest and best for 10s. 6d. postal. New Comet Star, Primrose, Sunflower, Dwarf Margaret Carnation, Cyclops Pink, Gail-lardia, Tulip, Popsy, Sunset Marigold, brilliant Dwarf Scab-pion, 1s. per packet; a packet of each for 7s., postal.—T. AXTON, Reading.

W. THOMPSON, Seedeman, Tavern-street, Flower Seed Catalogue is now published; it includes many interesting novelties, in addition to all established varieties. Should be seen by all lovers of hardy plants. No English Seed Catalogue contains so large a number of herbaceous and alpine plants. As evidence of the reputation his seeds have obtained, W. T. begs to state that he has received unsolicited and extensive orders for the Chicago Exhibition. Post free on receipt of a stamp.

SPECIAL CHEAP OFFER.—6 Geraniums, 6 Fuchsias, 6 Double Ivy Geraniums, 5 Yellow Calceolarias, 4 S. B. Calceolarias, 2s. 6d. free.—A. TOMKINS, Florist, Bidou, Kent.

GARDENING ILLUSTRATED.

ROSES.

SEASONABLE WORK FOR MAY.

Now that Roses are pushing into growth freely, and much warmer weather has set in, work among them has come on apace. The two chief points now are to keep the growth clean and to stir the surface-soil among them frequently. The latter has much to do towards the healthy appearance of Rose foliage, and materially assists the plants. Owing to the spell of fine weather—we being absolutely minus rain for several weeks past in mid-Sussex—it will be well to give a copious watering to Roses upon smooth walls. These are now in full growth, and with the wall's absorption of moisture as well as theirs, the soil has become much too dry in many instances. No half measures will do when watering Roses out-of-doors; you should either give them a thorough soaking or leave them alone. The green-fly has been very troublesome out-of-doors already, and must be constantly checked if good and healthy Roses are to be secured. Syringes frequently, early morning being the best time. There is no need to use a strong solution of insecticide; even clear soft water, applied with a fair amount of vigour, will knock off and kill many of these pests. It is much better, however, to use a little insecticide. Draw a little soil around dwarf stocks; also around newly-planted dwarf plants. This helps them very much, and is a great gain to the lower eye breaking into useful suckers later on. Brier-stocks should be loked over, and all superfluous breaks rubbed off. The stems of standard Roses are also more apt to push out Brier growth at this season than during any other part of the year; needless to say, these should be rubbed off as soon as they appear. Those of my readers who budded a few stocks last season, as per instruction given in GARDENING, must now afford the young Roses a due amount of attention. Dwarfs should have stakes inserted firmly, 2 feet to 5 feet in length, according to the height of the variety. The climbing Teas and Noisettes, also such strong growers as Ulrich Branner, Gabrielle Luizet, &c., among the Hybrid Perpetuals, will also need the taller stakes. In tying the young Rose to these great care is necessary at first. If drawn in too tightly they will break out at the union; if tied badly they will often fly out through the gradual pressure of growth. At the first tying do it only temporarily, and merely draw the young Rose in the direction of the stick. At the second time of going over them you can draw the Rose into its proper place and make a permanent tie. Maggot will be putting in an appearance during this month, and must be closely looked after, hand-picking being by far the quickest and surest remedy. Under glass Roses must have abundance of water, and a liberal supply of weak liquid-manure will be very beneficial. I would warn against applying liquid-manure while the plants are in a dry state; this should never be done, as the roots are apt to absorb it too quickly, and cannot

benefit to the same extent. Besides, it often injures them when the same strength applied while the soil was fairly moist would have done them good instead of harm. Give plenty of air whenever suitable now, but take great care to avoid the keen draughts so prevalent during May, especially when the wind is in a cold quarter. Slight shade should be given, and the atmosphere of the house kept rather moist. P. U.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR SHOW.

3665.—Standards: Should the plants selected for growing as standards have made their first natural break caused by the formation of a flower-bud at the extreme point of growth, which checks for a time the progress of the plants, and which is termed the natural break, the correct way to manipulate the shoots is to remove all but the strongest, providing, of course, the desired height—3 feet—has not been reached. Train up the new shoot quite straight, pinching out the point when high enough to induce other growths to be made, laying the foundation of the future head. Reduce to four the shoots which result from the topping, and when these have grown 6 inches long again top them, continuing this process until the requisite number of shoots are obtained to cover the trellis; but topping should not take place later than the middle of June. The number of flowers each plant is expected to produce must guide the cultivator as to the number of times the shoots should be topped; it is a mistake to attempt to produce too many blooms on one plant. It is far better to limit the number and have them of better quality. Plants of the small varieties of incurved kinds, such as Mrs. G. Rundle, if the heads are grown, say, about 2 feet in diameter, and about 1 foot 4 inches in depth, fifty blooms will be enough; but in the case of larger-flowering sorts, such as Jardin des Plantes or Lord Wolesley, thirty flowers on the heads would be ample, one bloom only being allowed to develop from each shoot. There are various forms in which the heads are trained; convex is, perhaps, the most suitable for general purposes. Bend pieces of strong galvanized wire of the length named over, fastening each to a circular ring as a foundation, and securing all to the top of a centre stake. Fix the framework from the bottom wire to the centre stake with the aid of two pieces of stout wire stretched across from one side to the other, as this prevents the head swaying about. Directly the plants are in their flowering-pots—10 inches in diameter—the framework on which the shoots are to be trained should be firmly fixed in the pots. Commence training the branches as soon as they are long enough, as the foundation is more easily formed at this stage than when the shoots are longer and harder. When the bloom-buds are formed, which will be early in September, dibble to one on each branch, and when they are swelling, give the plants their final tying, as the shoots will then have plenty of time to right

themselves, the blooms standing then fully 6 inches above the framework or head. In this way severe training is not so easily detected as it is if done a few days before the plants are in bloom. Specimens: As noted in GARDENING for December 3rd, 1892, the point should be pinched out of the plant when 4 inches high, repeating the operation on the new shoots when 5 inches long. Continue this until the middle of June, then cease, allowing the shoots to multiply at will afterwards. There are two methods of producing specimens. One is growing them to a large size, say 5 feet in diameter, with 200 blooms on each plant; the other is limiting the plants to about 3 feet in diameter, with from 30 to 50 blooms of high class merit, quality being the first consideration. Plants of this type are much more desirable than those grown for mere size, as the quality of the flowers must then be a secondary consideration, and plants unduly stretched out are ungrainy and not nearly so useful in a decorative point of view. By the middle of May the plants should be

PLACED OUT-OF-DOORS in an open position, safe from strong winds, but where they will have the full benefit of the sun. About the first week in June the plants will require their final shift into 12-inch pots for the largest growing kind; an inch or so less will suffice for those of medium growth. Plunge the pots half their depth in ashes; this prevents the soil drying quickly and keeps the plants firm, as it not secured in some way they are liable to be blown over in some situations. By the end of July the plants will be furnished with a large number of branches, some of them 2 feet long; at this stage they must be got into position. Commence by tying the branches out, having in view the size required, depressing them as may be desirable. Manipulated at this stage the branches bend more easily than they do later in the year when they get firmer, and when the plants are in flower bent stems are not so apparent as when training is done at a later stage. Bending the branches induces them to break into growth more freely. The plants make a natural break about the middle of August. The branches produced from this break will show a flower-bud about the middle of September. These are the buds which should be retained for the production of the flowers, retaining but one to each stem. Pyramids require the leading shoot topped at about 9 inches high, the best shoot following being taken as a leader again, the side branches trained out regularly. A wire hoop about 18 inches in diameter is fixed at the base of each plant, supported by two cross-sticks affixed to the pot in which the plants are to flower—10-inch ones—a central stake of the requisite height being at the same time inserted. Smaller wires can be taken from the hoop to the top of the stake, if desired, to which the branches can be secured. The last topping may be done as late as the end of June in the case of the late-flowering sorts, the earlier-flowered kinds a fortnight later. As in the case of the specimens one bloom to a shoot is sufficient; dibble to that in the centre, as being the best directly they are large enough to handle. Plants 3 feet high and 3 feet throughout at the base are large enough for any purpose. The details of potting, water-

ing, feeding, and housing the plants are the same in all methods of culture. The plants should now be in 6-inch and 7-inch pots, preparatory to being placed in those they are to flower in. The compost for the last shift should consist of three parts fibrous loam, one part of half decayed horse-mannure if the loam is heavy; if light in character that from the cow-house partly decayed is best. Add half a part of wood-ashes and charcoal mixed, and enough sharp silver sand to keep the whole porous. To every bushel of compost add 2 lb. Thomeon's or Innee's Vine-mannure. Drain the pots liberally and carefully, ramming the soil firmly into the pots. Water will not be required for at least a couple of days after potting. After that time do not allow the plants to suffer for want of it at any time. Syringes the foliage twice daily during hot and dry weather. When the pots are full of roots the plants need a stimulant of some kind. Scott-water, made by placing half-a-bushel of soot in a sack and soaking the sack in a tub of water, is beneficial to the plants. Liquid made from cow or horse-dung is also valuable. Failing either of these, apply some of the many artificial manures in the manner recommended by the vendors. Chrysanthemums like a change of food, so, whatever kind is given to the plants, do not continue the same sort more than a week at a time. Toward the end of September the plants will require housing. A cool airy greenhouse where the plants can stand near to the glass is the best position they can have. Abundance of air should be admitted at all times, and in the case of wet or foggy weather, if the hot-water pipes are made warm the air of the house will be rendered more hygienic, a circumstance all in favour of the free and perfect development of the blooms. E. M.

GARDEN WORK*

Conservatory.

There are several useful "follage" plants suitable for conservatory work and for general furnishing which may easily be raised from seeds sown now in heat. *Aralia Sieboldi* grows very freely from seeds, and useful stuff can be had in one year in 5-inch pots if helped on in a warm house or pit. *A. S. variegata* must be obtained from cuttings; root-cuttings will strike very well. *A. papyrifera* (Rice-paper plant) can be struck from root-cuttings each 2 inches long of the thick, fleshy roots. It is necessary in the case of *A. Sieboldi* to obtain freshly imported seeds, as old seeds will not grow. *Dracaena robusta*, *Dracaena Indica*, and other green-leaved kinds, the seeds of which are cheap, sown now in heat will be up to a fortnight, and if pushed on will make nice little stuff in 5-inch pots by the autumn, and may be transferred to 6-inch pots spring following. *Amorpha excolia* (Norfolk Island Pine) grows freely from good seeds, and in a small state, or till 5 feet or 6 feet in height, has a good deal of decorative value. Larger plants require a large house. *Cyperus altissimus* and *C. densus* are useful plants for filling fireplaces, or for furnishing dark corners. The variegated *Carex*, of which there are several forms, are very useful, and easily increased by division. *The Colusa* has been dropped by fashionable people, though two or three of the brightest coloured varieties will give character to sombre-leaved things. Very light and effective are the groups of plants confined to white and green. White common flowers are plentiful just now. *Spiraea* and *Dentaria* in a large mass, mixed with *Ferrea*, *Maiden-hair* and *Pteris*, are very effective, and may be used in contrast to groups of *Peiragonium*, *Fuchsia*, &c. The straggling groups of *Fuchsia* are always thick and make an agreeable change to keep the red and white varieties separate, using a foil of foliage for the light colours, and dark green foliage for the red flowers. Healthy young *Palme* associate very well with dark *Fuchsia*, and young plants of *Cyperus densus* also form a happy contrast to the light flowers. It is just as important to have plenty of the harder kinds of foliage plants to set as foils to the flowers as it is to have flowering plants enough to keep the house gay. Young plants of all kinds should be potted on. *Chrysanthemums* are now so scarce, and usually a long one. The plants must be securely staked, and should occupy a sheltered situation—i.e., sheltered from strong winds. It is possible to give plants, even in a dry time like the present, too much water, and a waterlogged plant is never of much use, so some care is necessary.

Unheated Greenhouse.

There is not much danger to be apprehended from frost now, and virtually, for the time being, all greenhouses are unheated artificially. Fire-heat, when used late in the spring, often does more harm than good, simply because the fire is not closed or watched, and the heat kept down during the day. If the house is closed, and the heat kept down in the afternoon, shutting up a good deal of the sun's warmth therein, even if there should be a few degrees of frost it will not penetrate the house. The growth of the plants where no fire-heat is used is generally fresher and brighter than where a fire is kept in a fluctuating kind of way. Tuberous *Begonias*, *Fuchsias*, and *Lilias* in variety, including *Asarum* and *Jacquinellum*, are now in the midst

of growth. Keep in a light position, and water sufficiently when required. *Hydrangeas* of sorts, *Myrtles*, and *Roses* are now working into position.

Stoves.

Rearsure the plants often, and that all may have space for reasonable development. Many things will do now in an intermediate house or warm greenhouse. Tuberoses coming into flower should have liquid-mannure. Shift on to larger pots the early struck cuttings of the usual class of winter-flowering plants. If kept moving as freely as possible good plants may be had in one season. *Violets* are showing plants in summer and will grow specimens are often useful in a collection of stoves and greenhouses at an exhibition. There are plenty of plants to select from now, but it is not always easy to make up a good dozen in August. Outtings of the young shoots of *Gaedenias* will strike now in bottom-heat. If there is a border or bare wall space anywhere set a plant or two of *Euphorbia Jacquiniflora* against it, and train it up *Eucharis Lilies* which require to be reported may have attention now. I simply shift on into larger pots, until they reach the largest size we have, where they remain, helped with liquid-mannure, for several years. The less disturbance there is at the roots the better. Use a rough, rich, open compost, with plenty of drainage.

What to do with Spare Houses.

If anyone is fortunate enough to have spare glass-houses, fill them with Tomatoes. These offer the best chance of paying expenses. Cucumbers also may be planted, but the two should not be planted in the same house. Tomatoes may be well grown in boxes. The best thing in this way are the Orange-boxes, which may be obtained very cheaply from the fruiterers. Rough old turf, with a little soot and bone-meal, will do very well for Tomatoes in a confined space. Leave room for top-dressing, and give what training is required regularly.

North House.

Very useful this cool structure has been during the last six weeks. Without many of the flowering plants would have lost their attractiveness much earlier than usual. After the *Azaleas* are over the house will be filled with *Pelargoniums*, *Fuchsias*, and *Heaths*, the latter standing on a stone slab along the front of the house, where they will have abundant ventilation, and where the man in charge can reach every plant with his knuckles when he goes round with the water-pot.

Window Gardening.

Window-boxes may be filled now, and kept under cover to grow and fill up before placing them outside. *White Daisy*, *West Brighton Gem Scarlet* "Geraniums," with *White Ivy-leaved* "Geraniums" and *Blue Lobellias* alternately among the front. The boxes may be varied by dropping in a *Yellow Daisy* or two, or *Yellow Calceolarias*, with *Pink Ivy-leaved* "Geraniums" instead of white. The *Ivy-leaved* "Geraniums" should be large enough to fall over the front of the box. Double-flowered *Nasturtiums* work well in along the front of the boxes for a change, and *Creeping Jenny* may be planted to fall over the front. Good soil must be used, and the boxes should be rather thickly planted. The plants inside the window which have done flowering may be set outside to ripen growth. At present the windows are gay with *Pelargoniums*. When these are passed *Tuberous Begonias* will be coming in, as will also *Fuchsias* and *Zonal Pelargoniums*. All things require more water now than they did a month ago. Small bushes of *Heliotrope* and *Mikrococtis* are very sweet. Some of the spikes of *Mignonette* now offered for sale are very fine.

Outdoor Garden.

The drought has been and still is very trying to many things. There has been unusual brilliancy among the spring flowers but it has been short-lived, and, in many instances, the bulbs may soon be removed and the beds got ready for the usual summer bedders. As the spring has not been so bright and warm, it is not unlikely some part of May, as a rule, may be cold and frosty, therefore avoid, if warning may be attained, about potting out bedding plants too soon. The Queen's birthday, 24th of May, North of London, at any rate, is quite time enough to think about bedding out; and in the meantime get the plants thoroughly hardened by exposure all day and on mid nights also. Crowded borders of *Herbaceous* plants, especially where the borders are narrow, margins round groups of trees and shrubs, have not been quite a success. Every four years, if the plants are to do any good, these borders should be overhauled, manured liberally, trenched 2 feet deep, and the plants rearranged as to afford a little more space to each group. It would probably, in most cases, be inconvenient to have larger groups of all the plants grown, as space could not be found for them, but some of the special things might be permitted to swell; and in this respect each might (I expect would) indulge his or her own taste. Personally, I should like to see large, bold groups of the hardiest *Lilias*. It is of no use to plant delicate things in the average garden. We will leave those for the wealthy amateur who can and does experiment.

Fruit Garden.

Much has been written about thinning Grapes; still, every beginner who has no old hand to give him a practical lesson has to fight it out, guided chiefly by his native intelligence. An objection from an old practical hand, who knows something of the Vines and the load they are able to carry is always valuable, but, fail this, the beginner has to do his level best with the information he has been able to pick up from papers, &c. One of the worst Grapes to thin is the *Alcante*—in fact, I should say it is the worst, and if not taken in hand in good time it will be very difficult to do it at all. Cut away quite two-thirds from large bunches. A good many berries must be cut from the centre of the bunch. *Hamburgs*, again, may have quite two-thirds of the berries cut out of large bunches if the berries are to swell to a large size. Grapes intended to keep late should be thinned more than if they are to be cut as soon as ripe. *Dust Muscat* of *Alexandria* over with the pollen of *Black Hamburgs*. There is always plenty of pollen on the latter, and if the *Muscats* are late in blooming some of the pollen must be collected from the *Hamburgs* and kept in a tin box till required. Keep a sharp look-out for the *Gossyberia* caterpillar, and apply

the usual remedies. *Hellebore* powder is the best and cheapest; may either be dusted on or mixed with water and passed through the syringe. The *Good Moth* will now be laying its eggs upon the young *Apples*, usually in the cup or eye of the *Apple*. Spraying with Paris green (a preparation of arsenic), used at the rate of one pound (a preparation of 200 gallons of water, or the proportion will be the same for small quantities. Will require more than one dressing.

Vegetable Garden.

There should be no French Beans in houses now, as I think the hot weather has made them unsafe to eat in *Vinerias* or *Peach-houses*. But if planted in pots and frames, French Beans may be had till they can be gathered on the south border outside. Draw earth up to *Potatoes* which are through the ground. *Sharp's Victor* in frames, will now be fit to dig. This is a good boiler, and the quality is excellent. Sow *Spinach Beet*, *Beet*, *Drills*, *15 inches apart*. Rampion makes a very nice addition to the salad-bowl. Sow now thinly in well pulverised soil. Scarcely any covering is required, as the seeds are so very minute. I generally cover by lifting a little soil over with a turnip riddle. The plant has a little tap root like a *Turnip Radish*, which may either be eaten like *Radishes* or be sliced up on the salad-bowl. It is most unlikely that some seeds may fail to grow. Where such failures occur sow again; first, thoroughly moistening the soil the evening before; next morning draw drills and sow the seeds, and shade with mats or canvas till the seeds germinate. Keep a stock in reserve of young *Cucumber* and *Melon* plants to fill frames as they become vacant. Erry bit of glass should be profitably utilized. Tomatoes under glass are pushing on fast. The season in planting and sowing is very considerable. Do not be in a hurry to set out Tomatoes outside. We shall probably have from weather with cold winds yet. *Cucumbers* in warm houses must have abundance of water both at the roots and also in the atmosphere. If the roots are started the fruits will be better. E. HODAY.

Work in the Town Garden.

All but the most tender description of bedding-plants, such as *Calceolarias*, *Alstroemerias*, and *Freesias*, ought now to be standing in 4-inch pots or frames, with more or less air given every day, and a little left on nights as it seems to harden them as much as possible. A very light shade over the glass may be necessary on bright sunny days, but the more sun they can stand now the better. The exceptions referred to above will still require a little artificial heat—at least by night, if out in the daytime—so even if the cuttings have not been inserted long they have still time to make good plants, as once rooted they grow very quickly, and it is seldom safe to plant out this class of subject before the middle of June. *Chrysanthemums* of all classes may now be safely exposed in the open air, having been gradually hardened in cold frames. The plants will now, for the most part, be occupying 5-inch or 6-inch pots, and should be getting nicely established in these sizes by this time. Backward plants in small pots may still be shifted on, as there will be nothing gained, even for exhibition purposes, by getting them moved into the flowering sizes for another month yet, and where grown for ordinary decoration or supplying cut flowers only, yet another fortnight will not be at all too late for the last shift. Some growers give their plants an intermediate shift into 7-inch pots, but I cannot see the advantage of this at all (unless in the case of exceptionally forward examples, or plants to be grown on into large specimens), as a strong plant in a "large 45 (6 inch), or "32" (6 inch) pot will go quite well into the 5 1/2 inch or 9 inch size in which the plants are usually flowered. If dwarf plants are wanted the stock should be cut down to within 8 inches of the pot about the end of this month, and be reported as soon as the young shoots are 2 inches long. Window-boxes should now be looked up, repaired, and repainted if necessary. Where the boxes are to be filled with soil and the plants set out therein time will be saved, and a display more quickly obtained, if the boxes are filled and planted at once, leaving them in the greenhouses until the end of the month; this will give the things a good start. Abundance of water is now required by pot-plants of all kinds. Water taken from the mains is often very hard, and where this is the case it is apt to impart an unpleasantly white appearance to the foliage, when freely used. Soft or rain water is far better, and though in towns this is generally so sooty as to be useless for any other purpose, yet it is just the thing for garden use, and should be carefully preserved. B. C. B.

THE COMING WEEK'S WORK.

Extracts from a garden diary from May 13th to May 20th.

Just commenced bedding out by planting the *Calceolarias*, *Asters*, *Stocks*, and a few other things which are very hardy, including a good collection of *Pentstemons*, which were struck in the autumn, and have been sheltered in a cold pit since. It is not wise to trust to old plants of *Pentstemons*. It is true I have had them pass through the winter without injury, but a few dozen or so of hundreds of cuttings occupy so little time and space that one need not be at the mercy of the weather. Of course, it is too early yet to put out anything tender, and that has not been early yet. Plants which have been properly hardened by gradual expansion will stand 2 degrees of frost. Spraying *Roses* on walls with soft soap and Tobacco-powder. The latter is as good for killing the insects who mixed in soap and water, and syringed over the plants as when used in the form of dust. Pricked-out for sowing *Primulas*. Made up hotbeds in pits to be ready for sowing *Melons* and *Cucumbers*. I always fill all spare pits and frames with something useful for the bedding plants in houses. The growth has been rapid, necessitating a good deal of pinching. Shifted on *Chrysanthemums* a number, using rough, early loam, enriched variously, which means that we are trying experiments with different manures. Planted a new house with *Tomatoes*. The house is only just completed; and as the plants were waiting, they were set out as soon as the borders were got ready. The house has been built for more than one purpose. After the *Tomatoes* are over the house will be filled with *Chrysanthemums*.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, but the quality of results.

followed on with Clocerarias and Primulas, and filled with Tomatoes again in the spring. Tbloned Grapes in a later house. I hope they have set well. I have used Hamburg pollen for the shy sesters. Cleared off bulbs for beds in the flower garden, and preparing them for Geraniums, &c. Have worked up a good stock of *Salvia patens* from cuttings. This is a delightful blue-flowered bedding plant one never has too many of. Earthed up Cauliflowers, Tied up Lettuces. Sowed Turnip Radishes. Planted Windsor Beans for last time. It is just possible, if later Beans are wanted, that cutting down some of the Long Pods will produce a new growth and a better crop of Beans. Mulched Peas with manure. Set out a couple of rows of Celery and half a dozen rows of Leeks with plants started in heat. Planted more Peas in succession. Dusted over Onion-beds with soot and nitrate of soda. Frickeed out a lot of young plants of *Azoreum japonica* sibs. The plants were raised from root-cuttings early in heat. Small bits of the fleshy roots planted like Leeks will grow freely. I have had flowering plants from such root cuttings the same season when started early. Staked out specimen Fuchsias. These are splendid conservatory plants, but they have lost caste of late years. Potted on Balsams. Looked over Peach-trees on walls to thin the shoots and fruits a little more. There appears to be a good crop of Plums if they will stop on. Large old trees would be improved by a soak of pond or river water.

3625.—**Hyacinths and Tulips.**—You may if you like keep the bulbs in the boxes, but

TREES AND SHRUBS.

CHOICE SHRUBS FOR BEDS AND BORDERS.

BEYOND the common tangled thickets of shrubs that are found in the majority of gardens, it is unusual to meet with any instances of special culture of the choicer things, which, if they manage to exist in the struggle with their rampant associates, have no possible chance of showing their true beauty. A general unesthetic appearance and lack of interest will always characterize our shrubberies until we alter our methods and realize the value of the many fine shrubs now in cultivation. The thick shrubbery should only be tolerated where it serves the useful purpose of providing a needed screen or covert. Even this need not be the dull, dreary, flowerless thing it frequently is, because vigorous trees and shrubs that are lovely and variable in leaf and blossom are plentiful. The object of this article, however, is more to give a selection of choicer

special preparation and some extra care, but such trouble is well repaid. The culture is simplified and good results are more likely to follow upon a plan of growing things like these in beds and borders, because the soil can be made up to their liking and there is no risk of other root-robbers coming in and devouring what was not intended for them.

AMYGDALUS AND PRUNUS.—The practice of budding and grafting these on needless and unsuitable stocks, and the consequent interminable sucker nuisance, are doubtless responsible for the great scarcity of these, the most lovely of spring flowering shrubs. We went them upon their own roots, and then they are sure to make pretty bushes and handsome groups. The little dwarf Almond is quite one of the early shrubs, putting forth its glowing rosy blossoms in days often dull, cold, and cheerless. Naturally it rarely attains a yard in height, but spreads and suckers freely, so is not difficult to increase. It ought to be a popular shrub. Later on comes *Prunus triloba*, with rosy rosettes studing its slender shoots.

Hydrangea hortensis as a lawn shrub. (See page 140.)

the usual way is to lift them when the leafage has died down, and store them in a dry place during the summer months. You did not say whether they have been forced? If so, you could not very well use them again next season, so it would be better in the autumn to plant them out in the garden, where they will be useful. But if they have not been forced hard they can be used again for the same purpose.—C. T.

3605.—**Flower-pots.**—If you consult the advertising columns of GARDENING you will doubtless discover what you want; but, of course, there is no special merit in pots that are ornamental, and they cost more, and also occupy more space. They are all very well for window-boxes, for spots where the common garden pots would be unsightly. There are many very beautiful designs in pots, and the price depends upon the extent of the elaboration. A good firm is located at Weston-super-Mare. It used to be Mr. Matthews, but he retired, and I forget the name of the present firm. Splendid things in the way of ornamental pots used to come from this place.—C. T.

things, such as we might plant in groups in beds or borders either by themselves or associated with the vigorous and finer families of hardy flowering plants. Not a few would admirably adorn the larger, bolder rock gardens. In a large garden I once visited, all the dwarf, choice conifers had been planted in the way here suggested, whilst the commoner types were also plentiful. The place was altogether overdone with vegetation of this kind. Had flowering and deciduous shrubs been planted in the same way, the garden would have been doubly beautiful and most interesting.

DAPHNES are certainly worthy of the best attention we can give them. The oldest, the best known, and most deservedly popular is *D. Mezereum*. To see this at its best, there should be a group of from six to twenty plants. It is lovely alone, but gains in effect if interspersed with the Partridge Berry (*Gaultheria*), which hides the ground, has ample leafage, and is altogether a charming foil to the profusely-bloomed, but leafless bushes of *Mezereum*. A trio of choice kinds exists in *D. Genkwa*, *Blagayana*, and *Cneorum*. They need a little

Upon the Plum-stock its life is a struggle, usually ending in death; but on its own roots we need not hesitate to plant a group. Beside it will come the little Chinese Plum (*P. sinensis*), a slender, graceful plant with flowers of the purest white, preference being given to the double-flowered variety, although both are highly ornamental.

GENISTEA.—Among these there are several species which are well adapted for the rock garden or choice border. They root deeply, and even in poor soils often do well. There is a lovely double-flowered form of the Common Dyer's Weed (*G. tinctoria*), and it is grafted standard high on the Laburnum. It is infinitely better to plant a group in a bed or on a border. Beside it or near at hand would come *G. praecox*, which is one of the most charming dwarf shrubs of May. It grows into a dense spreading bush, and each season is liberally sheathed with clear sulphur-coloured blossoms borne in racemes. *G. radiata* is another little-known, but pretty species. It is bushy in growth, with graceful arching shoots which are clothed with finely-cut leaves. The flowers appear in the axils of

the leaves and are of a soft canary yellow hue. Last, but not least, comes the Spanish Furze (*G. hispanica*). It is a low-growing kind, rarely exceeding 1 foot in height, but it is hardy, if small, and tenacious of life, rooting deeply if at all favourably planted. It flowers in June, and the little bushes are then covered with gay golden-yellow blossoms.

RUBUS.—The Rocky Mountain Bramble is a lovely shrub, needing a wall in some localities, but it can be grown as a bush in many places if planted on a sunny border. When so planted it will probably not exceed a yard in height. Its great white flowers are each nearly 2 inches across, like single white Roses, and they have the additional charm of sweet fragrance. *R. odoratus* (the purple-flowering kind) also makes a pretty mass, but it is, perhaps, best kept separate, as it is rather vigorous. The Nootka Bramble associates well with it, for, though not quite so strong growing, it can hold its own, and the two blend into a pretty mass, the fine single white flowers of this last species appearing in striking contrast to the purple ones, whilst the handsome foliage of both is worthy of admiration.

OLEARIAS are a numerous family from the Southern Hemisphere, and those that we know to be hardy are most ornamental, growing into neat bushes, and producing flowers so much like those of a Daisy, that they have been aptly called Daisy-bushes. At present the actual hardness of several species is not known, and experimental planting with a view to testing is desirable, as we want all we can get of such lovely things as these. Concerning *O. Haasti* no doubt exists. It is a delightful shrub, always pretty as an evergreen bush, and during the latter part of summer as white with blossom as it often is when wreathed with snow in winter. Though dense and dwarf, it soon makes a good bush or group if planted where it has nothing to contend against. *O. stellata* is better known under its original name of *Eurybia*, which clings to it, and is likely to be used, although botanists now classify it under *Oleoria*. But whatever it is called, it is a shrub that many should try in a sunny spot upon the rockery or border. It has a small crimped leaves and flowers considerably larger than those of *O. Haasti*, in size as well as shape resembling those of a Daisy. The flowers are pure-white, and they appear quite early in summer, each one lasting for some time. A little trouble would be well repaid if it resulted in a flourishing group, and such shrubs as these merit attention and encouragement.

CISTUS and **HELIANTHEMUS** are well adapted for sunny, dry banks and borders. Of the first named, such species as *florentinus*, *formosus*, *oreticus*, *monspeliensis*, *calvifolius*, *ladaniferus*, &c., are some of the prettiest of flowering shrubs. Their liability to injury from cold in winter will check their general or extensive cultivation, but where they are found to thrive it would be wise to make them a feature. A slight protection helps them considerably, and this is easily afforded if the best kinds are closely grouped. Upon mounds or banks they often thrive beautifully. *Helianthemus* are quite hardy, but of low stature. In the way of dense, dwarf-spreading, profuse-blooming shrubs nothing can surpass them. They are simply magnificent in the early summer, and the thoughtful planter would blend them into some striking associations. They give us single and double flowers, and an infinite variety of shades of colour, from pure-white and cream to the richest yellow and deepest orange, from palest pink to rich rose. They grow so freely almost anywhere, except in the shade, and they are increased so easily from division or by cuttings, that it is surprising we do not see them largely planted.

KERRIA JAPONICA (the Jew's Mallow) is another of the lovely shrubs of spring, and though we see it against a wall or fence, we do not see enough of it. It does not need protection, except in very cold districts, and, therefore, should be planted in a group. There are single and double-flowered kinds, the former being the more neglected of the two and undeservedly despised. It is decidedly pretty when seen growing and blooming under favourable conditions and away from needless restrictions.

HYDRANGEAS may be grown by many more than they are at present if they are planted out in a bed or border of good soil, which is well drained in winter, but open, sunny, and damp

sheltered. In a well-drained soil and in a situation favourable to the ripening of the wood in autumn, *H. hortensis* (see page 139) will stand a considerable amount of frost and not be injured. The type is well known, and there are several varieties equally fine, such as *stellata*, *Otakea*, and *Thomas Hogg*. The Oak-leaved *Hydrangea* from America, too, is very uncommon, but beautiful, distinct in leafage, with handsome clusters of white flowers. Then there is the hardest kind of all the Japanese species—*H. paniculate grandiflora*. It should have a level spot, a deep soil, be annually cut down, heavily mulched, and watered if very dry weather prevails in summer, and then during autumn a group will be one of the most conspicuous things in the garden.

VIBURNUMS are useful flowering shrubs and fairly popular—at least, the sterile form of *V. Opulus* is—but a charming and choice kind for grouping is *V. plicatum*, a native of Northern China. It is a shrub of great merit. It makes a handsome dwarf spreading bush, well clothed with leafage, wrinkled like that of the Wayfaring Tree (*V. Loutana*), and in the early summer months every branch is wreathed in clusters of blossoms. Individually the flowers are larger and whiter than those of the Snowball Tree (*V. Opulus*).

FORSYTHIAS—The loveliest of these is the slender, graceful *suspensa*. We value it as a plant for covering walls and fences, but many err in supposing it should not be planted away from support. It will make a bush and a pretty group if several are planted, its long shoots being as thickly studded with clusters of golden bells as they would be against a wall. *F. viridissima* is an erect growing species with yellow flowers similar to those of *F. suspensa*, and it would not be a bad plan to let the two mingle with one another.

PERNETTYAS are perfect shrubs for beds and borders. They are evergreen, always fresh and neat in appearance, pretty when bearing their waxy blossoms, but ten times more beautiful when laden with their profuse crops of berries. The variety is great and the value of the family proportionate.

GAULTHERIA has been mentioned casually in a suggested association with the Mezereum, but it is worthy of individual notice. There are two species, *G. Shallon*, which let alone grows a yard or more in height, and bears pretty white blossoms, succeeded by berries. *G. procnemba*, as its name implies, is of procumbent or trailing habit. Both are choice, and may be planted with good effect.

RUSCUS RACEMOSUS, or the Alexandrian Laurel, is a pretty shrub to associate with other things. It loves the shade, but is not particular as to soil or site, and would be found useful in many ways.

If we add to these the choice dwarf *Contousters* and the *Mahonias*, and for fragrance include *Rosemary*, *Lavender*, *Southernwood*, the *Sweet Gale* (*Myrica*), and *Sweet Fern Bush* (*Comptonia*), we have a selection of great value. The flowering season of the things here mentioned begins in the early weeks of the year with the Mezereum, and concludes with the *Hydrangeas*; while through the depth of the winter some things are bright with berries.

A.

Clematis montana.—Ten thousand flowers from a plant in beauty for a whole month is not a had result, at a cost of 2d. for some cuttings brought me by a boy six or seven years ago from a semi-wild plant, growing in a wind-swept village on the sea in the neighbourhood. Each individual flower is admirable in itself, of pure white, and from 2 inches to 4 inches in diameter. It is earlier this year, its proper blooming period being throughout May. It has been trained in line to suit the house, and the shoots now reach 50 yards. The immense quantity of bloom has a striking effect, both by night and day. In the sun it is gorgeous, and at night it gives the appearance of snow, and makes one feel as if it were winter. Its treatment with me was to plant a rooted cutting over the roots of an evergreen Oak, which has been cut down to within 6 feet of the ground, in a soil of the poorest description, already thoroughly exhausted by the Oak, training it up this trunk, and thence onwards on the strong galvanised wire attached to the house. Curious remarks are heard in the road

opposite the house regarding the flower: "It is artificial!" "Why is the house decorated?" &c. An amateur who has been in all parts of the world said it was the most floriferous plant he had seen. Grown in a cool-house the flowers are even of a purer white, and then it flowers during March; but in a couple of years it outgrows the accommodation a pot affords, for it must not be cut if flowers are wanted; but even after flowering its foliage is of the handsomest. About one in ten cuttings strike in the open; this is my experience also of the larger hybrids. Its roots should be kept moist and cool by rough stones being placed over them, or by being grown on the north side of a wall, hanging untrained from which, in the sun, it is seen in perfection. The town of Clifton boasts some fine specimens growing over trellises on houses.—A. STEWART.

Two beautiful Pyruses.—One of the most beautiful of all is *P. Malus floribunda*, a Japanese tree, and remarkably free blooming. It does not grow many feet in height, and makes a dense head, the flowers crowding every shoot. They are tender pink, the buds of a crimson colour, and the contrast is very charming. The best variety is *atro-purpureum*, of which the flowers are much deeper in colour, quite a rose-purple. A few examples of this *Pyrus* should be in every garden. It will grow in almost any soil and position, whilst it is perfectly hardy. Another valuable early-flowering species is *P. Malus spectabilis*, which has, at this season, a profusion of large rose-tinted flowers wreathing every branch. It is singular that such a lovely tree is not more popular in gardens, as it is worth planting freely in both large and small places, thriving with vigour in all ordinary positions.—C. T.

3551.—**Aucuba japonica.**—The *Aucuba* is not a Laurel, and the two plants belong to distinct natural orders. The *Aucuba* to the *Cornaceae*, and the *Laurea*, or *Bay-tree*, to the *Lauraceae*. *A. japonica* is known by several names, as the *Spotted Laurel*, the *Gold-leaf-plant*, *Blotched-leaf Laurel*, and *Variiegated Laurel*. It is usually called by the latter name. The way to get the plants to berry is to plant male and female varieties together, and you will soon find that you will get a show of the crimson fruits. A well-berried *Aucuba* possesses considerable beauty, and the berries remain bright in colour over a long season.—C. T.

3578.—**Virginian Creeper and Pyrus japonica.**—*Virginian Creeper*, especially the common variety, will grow very freely, either from cuttings of the old wood in autumn, or the young shoots in summer, in the frame. *Pyrus japonica* is more difficult to strike from cuttings, but it is easily obtained from layers by pegging some of the young shoots down round the base of the plant.—E. H.

—You can easily raise *Virginian Creeper* by layering the thin branches, which will root at almost every joint. *Pyrus japonica* may be rooted from cuttings put in firmly on a shady border. In two or three years these will produce good, strong plants, which can be trained on a wall or fence.—A. G. BUTLER.

Earliness of the season.—The earliness of this season is so unusual that I think it may interest readers of *GARDENING* to know the dates on which some *Roses* have flowered with me: *Yellow Banksian* on April 3rd, *Rève d'Or* on April 12th, *Maréchal Niel* on April 17th, *Safrano* on April 17th, *Cheohunt-Hybrid* on April 26th, *Jaune Desprez* on April 24th, *The Bride* on May 1st, *Lamarque* on April 29th, *White Rugosa* on April 30th, *Red Rugosa* on May 2nd, *Alba Rosa* on May 3rd. These *Roses* are all on south walls, with the exception of the *Red* and *White Rugosa*. The blooms of the *Banksian*, *Safrano*, *Jaune Desprez*, and *Cheohunt Hybrid* are unusually fine, those of *Rève d'Or* smaller than usual, and the *Maréchal Niel* poor. The earliest *Rose* to flower last year (1892) was *Rève d'Or* on the 25th of May.—C. B.

3582.—**Sawage in a garden.**—In its present state the sawage may be too strong, but if soil is usually diluted. Certainly, sawage may be applied with advantage to any strong rooting subject capable of taking it up and utilizing it, or it may be used for dressing land intended for such crops as *Turkeys*, *Cabbages*, *Broccoli*.—E. H.

3581.—**A plague of caterpillars.**—*Jewel's Gardeners' Friend* should smother the caterpillars if the branches are all wetted with it. Heliole powder is the common remedy, and is either dusted among the branches or mixed with water, and syringed underneath the branches. It takes two people to apply this or any other remedy properly. One to lift up the branches, and the other to apply the remedy with a syringe or other

FRUIT.

THE GOOSEBERRY.

THIS, to many, is the best of all fruits, and one, according to my estimation, far too much neglected in even good gardens. It is not only the cottager's friend, but at the same time fit for any nobleman's table. The culture of the Gooseberry, unlike that of the Vine, entails little or no expense; after being carefully planted, all it needs is good attention in the way of an annual top-dressing of rotten-manure and pruning, or, I might say, proper thinning out of useless wood. Pruning has been very much altered of late years; now, in most cases, the bushes are merely thinned, all misplaced and cross branches are cut away, and as much fruit-bearing wood left as is consistent with the strength of the plant. The thinning of the wood is no doubt good practice when fruit in quantity is required and where it is used in a green estate, but if fine, large, well-flavoured berries are the desideratum, the bushes ought to be kept quite open in the centre, and the main branches should extend quite apart from each other, thus allowing the admission of plenty of air and sunshine to impart flavour, which is so much valued in a Gooseberry. Another point where handsome fruit is desired is to thin the fruit well. This is rarely attended to, but are not Peaches, &c., thinned? Then why not the Gooseberry? This thinning process is all the more necessary in the case of bushes of

four or five leaves each and then stop them. The side growth may also be stopped at the second or third leaf beyond the hunch. Those laterals not having bunches on may be allowed to develop six or seven leaves each. It was a mistake to put drainage in an inside border, seeing that the Vines depend on watering for all the moisture they get. You will require to increase the depth of soil in the border to 2 feet.—J. C. C.

3662.—Keeping Apples.—Of course, you have doubtless good reasons for keeping the Apples so long, but they will not be fit to eat. I have tasted Apples kept so long, and although preserving a fair exterior they have been positively unpleasant—at least, quite devoid of the crisp, juicy, and agreeable flavour looked for in all good eating Apples. Some of the best preserved collections I have seen have been kept in a span-roofed house, running east to west, cool and equable in temperature. Coolness is of great importance, as if the temperature is high and dry at the same time the fruit will soon shrivel. Much depends upon the soil and situation of these trees, but in that question I cannot enter now. Keep the fruit cool—if damp it will not matter—and in a temperature that varies little. This is the best position for them. Look at them occasionally to remove all those that show signs of decay, as one bad one will in time contaminate many.—C. T.

3666.—Melon "Little Heath."—This is the best Melon for an amateur to grow, as it is more hardy than some of the varie-

The greatest difficulty is with regard to ventilating the frame, as without you make the most of the heat of the sun you are not likely to succeed. Give a little air at 8 a.m., and close it again in dull weather at 3 p.m.; but when the sun shines brightly do not close it until five o'clock, and at the same time damp the foliage and the sides of the frame with warm water. If you are much away from home in bright weather, place a double thickness of fish-net on the glass to prevent the sun from scorching the leaves. Give the roots a good watering once a week when the weather is hot and dry, and about once in ten days when the external temperature is cool and moist.—J. C. C.

3675.—Black Hamburg Vine-leaves withering.—Air should be given to vinerias before nine o'clock in the morning. A house full of pot plants should have a little air as soon as the sun shines full on the roof, so as to raise the temperature inside, or, say, not later than 6.30 in the morning. Ventilators opened a couple of inches along the back of the house at the highest point will be sufficient to start with, but the openings should be increased by 8 o'clock, and full air should be given on bright days by 10 o'clock. This air-giving by piecemeal, as it were, is very important. Cold draughts can and should be avoided. A cold draught rushing through a house that is kept closed till 9 o'clock a.m. would be likely to damage the foliage. Then, again, if the Vines are cared for, 5.30 p.m. is much too late for closing. The ventilation should be reduced at this season by 3.30, and the house finally closed and damped down by 4 o'clock. Reduce the number of pot plants in the house as soon as possible.—E. H.

I think you will prevent the Vine-leaves withering if you ventilate the house earlier in the morning; 9 a.m. is too late during such bright weather as we had in April. It does not give time for the leaves to get dry before the heat rises sufficiently to cause the scalding of which you complain. Should we get a recurrence of such weather again, you had better leave a little air on the top ventilators all night. Shut up half an hour earlier and open the top ventilators again about 8 p.m. or 9 p.m.—J. C. C.

3669.—Stopping a Vine.—This is an easy part of the work of a gardener, and when the process is explained anyone can do it. Some Vines are more fruitful than others, and strong, vigorous plants of a particular variety will be more fruitful than plants not so well grown. For instance, a vigorous-growing Black Hamburg Vine or a Muscat of Alexandria will show two and often three bunches on each lateral growth. The treatment I usually pursue is to pinch off all but one bunch, that nearest the base of the lateral, and stop the growth at the second leaf beyond the hunch. It will soon start to grow again, but must be stopped at once, continuing to stop all the fruits as fast as they are formed. It is bad management to let the laterals grow until they have to be cut out with a knife. Stimulants may be applied to the roots until Grapes have passed through the stoning period. As soon as the Grapes are thinned they grow rapidly; but when they arrive at a certain stage they stop growing apparently, and scarcely increase in size for about six weeks. This is the stage of growth at which the stones grow to maturity inside the berries; gardeners call it the stoning period. The Vines are, of course, as actively employed in developing the berries as they are at any other time, only the growth is not perceptible.—J. D. E.

The leading shoot ought not to be stopped until it reaches the top of the house. Lateral shoots growing from the joints should be pinched in at the first leaf, which serves the purpose of plumping up the eye on the main-rod. These will produce growths next season for furnishing the rod with side-shoots and give bunches of fruit if desirable. If the Vines has any side-branches these should have the point nipped out of each above the second leaf past the bunch, if any, to concentrate the energy of the Vine into the bunches of fruit. If there be no fruit on the side-shoots, pinch the point of each at the fifth leaf, and all lateral growths above the first leaf. The pinching-in of the shoots should be carried out when they attain the length described, whether the Vines are in bloom or not. It is really too early to use stimulants at the roots in an outside border; not until the berries are thinned

Fruiting-branch of Gooseberry "Roseberry."

pendent habit, which in many seasons are so weighed down with fruit that it is utterly spoiled by lying on the ground. The spade ought under no circumstances to be used in a Gooseberry plantation. Early in the season apply a top-dressing of good rotten manure, thus causing the fibrous roots to find their way to the surface and invigorate the plant. Check all weed growth by means of the hoe, and there will be no necessity whatever to have recourse to digging in any form either with spade or fork. Roseberry (here figured) is not very well known, but it is very sweet and pleasant, the fruits green, small, and freely produced. Winham's Industry, a free bearing kind, has been largely planted by market growers on account of the early swelling of the fruit. Private gardeners ought also to plant this variety largely in the ensuing autumn, as early Gooseberries for pies are always appreciated.

T.

3683.—Management of a Vine in a pot.—I presume there is a reason why you have not planted the Vine already. If there is not, and the border is quite ready, why not plant it at once? You would then get a better crop of Grapes next year. If you must keep the Vine in the pot this season it ought not to be allowed to carry more than four bunches of Grapes. Seeing that the rods are already a good length you will gain nothing by allowing them to extend. Allow the two leaders to develop

ties. You probably know that Melons like a rather heavy loamy soil, but I have seen very fair crops obtained from a much lighter description of earth. In the first place cover over the manure in the frame 2 inches thick, then put a mound of the same kind of material in the middle of the bed 6 inches in depth, and a fortnight later put a sufficient quantity to cover the bed all over the same thickness as the mound. If the frame is 6 feet by 4 feet two plants will be enough to furnish it with growth. Do not give much water at first, which should always be warm, and after the first three weeks do not wet the soil within a circle of 6 inches round the stems, or canker may attack them, and after the growth reaches the sides of the frame give most of the water near these parts. When the plants have made six leaves each pinch off the tops; the growths resulting from this stopping will furnish fruit after they have grown from 1 foot to 18 inches long. If one or two fruits show in advance of the others pinch them off; what you want to furnish a crop of fruit is to have several flowers opening at one time. You must allow a sufficient number of young shoots to remain to cover the surface of the bed; but they must not be crowded, and you must remove those which are not showing any fruit, and those growths on which fruit is swelling should be allowed to grow on without stopping. When the fruits are the size of a hen's eggs, place them on in a shallow flower-pot. Six fruits are as many as a strong plant can swell to a suitable size

the Vines need stimulating food, and not then if they are but recently planted. Except in very dry summers, Vines growing in outside borders do not require stimulants in any form; to supply them to young Vines is only to incite them to make gross and immature growth, which cannot produce satisfactory results in the shape of compact, well-finished bunches of fruit.—S. P.

— The time to stop Vines is when three leaves have been made beyond the bunch. Sometimes the young shoots are stopped just beyond the first leaf, but two leaves beyond the bunch are better. Do not let the shoots extend beyond the point named before stopping, as it wastes the strength of the Vines to let them make growth to any extent that will afterwards have to be cut back. This is the best time, from this onwards till the berries are etoned, for using stimulants. I shall give two or three dressings to late Grapes from this till colouring begins.—E. H.

OUTDOOR PLANTS.

3113.—**Flowers for a wall.**—If "Armine!" has an old brick or stone wall full of chinks and with mossy growth, such a wall may be made exceedingly beautiful with permanent perpetual things at small cost and with little trouble. There are many things more lovely and better suited for the purpose than those suggested in the query. Having done some amount of wall gardening of this kind, I will give my experience and hope that others besides "Armine!" may find a useful hint for future guidance. In the garden now under my charge there are some old stone and brick walls that are level for nine months in the year from one plant alone—that is, the Common Fumitory (*Corydalis lutea*). In the early days of spring it puts forth its elegant leafage of the tenderest green colour and as graceful as a maiden-hair Fern, and then comes a long season of bloom, when its tufts are sheathed with yellow. It is readily established by sowing seed in a crack or chink. To this, the original mantle of the wall in question, several things have been added, but none with greater success than *Eriana alpina*. This gem of the alpine flora perishes from damp upon level ground, but on the wall it is happy always, spreading into cushions and from new and for the next few weeks charming in blossom. The type has purplish blossoms, but there are also two lovely varieties, one of a bright rose colour and the other pure white. They were established merely by scattering or blowing seed into the cracks in spring or early summer and when the wall was moist after rain. The plants appear in a few weeks, and flower the following year. The Cheddar Pink (*Dianthus cæsius*) is a charming wall-plant and plentiful too in places, as, for example, about Oxford, where I once saw it blooming freely on a wall by the roadside. A gem of wall-plants is the Balaic Sandwort (*Arenaria balcanica*), for, not contenting itself with the chinks, if the wall is moist or shaded it creeps over the entire surface, making a close veil of the richest green. A few years ago I assisted in building two little walls, ostensibly to support two benches on each side of a path. Stone was used, and the joint and interstices packed with turfy loam as the building proceeded. No actual attempt was made to see how pretty it could be adorned, but the whole thing was hurriedly done, and any plants that happened to be at hand were put in the joints as the wall was put up. It has been a source of great delight ever since, and at the time of writing is such a picture as I never saw before. There are yards upon yards (square) of the little Sandwort now studded with myriads of tiny white blossoms. Mossy Saxifrage, and Sedums, Thymes, Arabis, and Phloxes, are perfectly happy, and even a stray piece of Gentian acanthe finds a congenial home, and with its flowers open on a sunny day recently, I could not help thinking what a glorious display it would have made had it been planted in quantity. On the top of the wall, which leaned against the bank, tufts of Auhrietia were planted, and here and there they hung down the wall, making a rich and lovely veil of blossoms for several weeks. Two more things occurred to me that I have seen most charming on old brick walls—namely, the red Valerian (*Centaurium rubrum*) and a little Alpine Tussock (*Linaria alpina*), a gem

among plants of the greatest beauty. One thing to be borne in mind is this: In endeavouring to establish plants upon existing walls seed will be for the most successful. It is useless to push plants into cracks with a little soil around them; they perish before they can establish themselves. The seedling makes a gradual growth, the roots naturally and of necessity going far down into the crevices and finding food and moisture sufficient for all vicissitudes and changes. Seeds of forest trees will grow upon walls and the plants even displace the masonry. This, of course, should not be allowed, but it teaches us that much more might reasonably be attempted with flowering plants of lowly habits.—A. H.

— The plants named will succeed in the position mentioned; but Pansies like a little shade and moisture, if possible. In addition, you might have many of the ordinary border plants, such as Phloxes, Michaelmas Daisies, Denericums, Hollyhocks, Perennial Sunflowers, &c., which would all succeed well in this position, as well as the things that you have mentioned. As regards the wall, it depends much upon its height what would be the most suitable, and you can have a variety of pleasing things. Veitch's Virginian Creeper would cling well, and it is very bright-green throughout the summer, the foliage changing to rich crimson shades in the autumn. Avoid the stronger, rampant-growing kinds. The Chimonanthus fragrans grandiflorus smells sweetly in the winter, when its curious yellow flowers are borne on the naked shoots. Jackman's Clematis, remarkable for the deep rich blue colour of the flowers, makes a fine show, and, if you care for them, you might have a few variegated Irises, or one green-leaved kind, such as Emerald Gem; but, of course, the quantity of things planted depends upon the length of the wall. The yellow-flowered Jasminum nudiflorum makes a brilliant show with its yellow flowers, and seems to live in the most congenial spots. In the poorest of soils and bleakest of positions I have seen it thrive well, and make a great show of colour with its rich yellow flowers. *Kerria japonica* fl.-pl. is a brilliant orange-yellow climber in full beauty in the spring season; it is commonly called the Jew's Mallow. The Fiery Thorn, or Pyracantha (*Orategus Pyracantha*), is very often seen on walls, and bears a quantity of orange-scarlet berries, whilst the leafage is very abundant and of a dense green colour. It will succeed in most places. Then you can have also *Pyrus japonica*, which makes a bright display of its scarlet flowers in the spring months. This list includes a few of the common wall climbers, and all are well worth growing, thriving in ordinary positions. Any of the kinds mentioned may be selected if the number is too large.—C. T.

3609.—**Watering a garden.**—Well, certainly, it is advisable to water the garden, Grass, &c., and the best time to do this is in the evening. It is not wise when the sun is shining full upon the garden, and a keen east wind is blowing, to water the plants; but some things unless watered would soon perish, especially those newly planted. If there is any probability of a frost at night, then you need not water, and in any case it must be done cautiously. A good plan is to break up the surface soil gently with a hoe, as it gets much caked during this hot and dry weather. I give my Pansies and herbaceous things, planted early in the spring, a good soaking three or four times a week, and without this assistance they would never make much progress.—C. T.

— Irrigation in a dry time when well done is undoubtedly beneficial; but there is a good deal of watering done which would be better undone, because it is not thorough. Merely sprinkling the surface in a dry time like the present is worse than useless. Better use the hoe and thoroughly break and pulverize the surface for it to act as mulch to check evaporation. There is moisture enough in the ground now a few inches down, and the roots will find it if the surface is well broken up to keep out the sunshine and prevent the crust from cracking. But there is watering which, I think, may be done with advantage. If recently-planted things are not watered they will die. Then, again, fruit-trees heavily laden with blossoms will, I think, benefit from a good soaking of water containing a little weak stimulant. I have generally found those trees the roots of which are

kept moist set their blossoms better than others which had received no attention, and all trees grafted on dwarfing stocks must be kept moist. Meeknom-growers generally break up the old beds, and mix the manure with burnt earth or cherted material, and when well blended, using it as a mulch over the roots. Much good may be done where the soil is light and dry in this way. Whenever it is necessary to water anything and the ground cannot be mulched, take the hoe early next morning before the sun has dissipated all the moisture, and break up the surface.—E. H.

3673.—**Lily of the Valley in a bed.**—Of course it would be much better to thin out the Lilies. The quickest plan would be to trench out the roots in belts about a foot in width both longitudinally and transversely, filling in with good rich soil; but, of course, the wester plan would be to dig out the whole of the roots, enrich the soil, select the strongest stools, and replant these about 6 inches apart over the whole bed.—A. G. BUTLER.

— The Lilies are too thick to flower satisfactorily. Although it is late for transplanting them you will gain a little time if you remove a portion of the plants at once. You must, however, be prepared to shade and water them for two or three weeks after planting. So treated they may not flower much the next year, but they would be much stronger the year after than those planted next autumn or spring. You must dig and manure the ground before planting, and then the plants will not want any more manuring for two years.—J. C. C.

— The best way of thinning Lily of the Valley is to take them all up and divide into small clusters of crowns, and plant them from 9 inches to 12 inches apart in fresh soil well manured. February is a good season for transplanting. Another way of thinning thick beds of Lily of the Valley is to cut out strips 8 inches or 10 inches wide, leaving strips the same width undisturbed. The roots lifted may be planted elsewhere, and the soil made up by topdressing with leaf-mould.—E. H.

— The plants certainly require thinning now, and you cannot expect good flowers if the beds are systematically neglected by being allowed to get so that it is impossible to discover the blooms. Fifteen years is too long, and from eight to ten is, as a rule, quite long enough. You did quite right, too, giving manure, but it would be best to let the plants have a thoroughly renewed soil. Moderate shade and moisture suit the Lily of the Valley best, and a good leamy soil, enriched with manure, will afford excellent results. The time to plant is early in the autumn, just after the leaves have decayed, and this is the time to divide the clumps. You will be able to get a good lot of crowns from your bed, and when you plant again, put them about 3 inches apart, as then they will not become crowded together so quickly as would otherwise be the case. A good dressing of well rotted manure on the bed after planting will be an advantage, and bear in mind the importance of plenty of water, not forgetting liquid-manure, which tends to promote fine spikes. Such treatment as this is necessary, however, of course, only if you want to get better flowers than the miserably thin spikes one sees as a rule in ordinary gardens. Under this system the plants will remain in condition for several years, and annually give a good supply of the pure white fragrant flowers.—C. T.

3629.—**Creeper for a trellis.**—There are not a great many things that would succeed in this position, but Veitch's Virginian Creeper would grow well, and it is tidier than the other Ampelopsis, which are unruly and coarse. You might try also *Jasminum nudiflorum*, Clematises, C. Jackmanni, which I should think would do well. If you prepare the soil a little for the plants, *Kerria japonica* fl.-pl. would grow well, also *Clematis montana*. As you say the soil is thoroughly root ridden, you must make it fairly good by giving plenty of manure, and after the plants are put in, give plenty of water during the succeeding weeks, to assist them to become well established quickly. You could plant out now from pots and get good healthy examples.—C. T.

3680.—**Spanish Iris.**—This Iris is a beautiful garden flower, which is being more largely grown than has been hitherto the

case. It is a native of Spain and Portugal, and has long been in English gardens, although many of the beautiful kinds are pronounced of Dutch origin, as the growers there have given much attention to bulbs in general, and Tulipe in particular. It is a golden rule not to disturb them when they are once planted, certainly not until it is seen that they are in need of lifting. Irises, as a rule, hate constant disturbance at the root. The same cultural remarks that apply to this Iris apply also to the English Iris, which is a beautiful flower, with broad segments, and is a charming companion to the Spanish Iris; let me remind you they are both "Spanish Irises." The name "English Iris" occurred through the Dutch supposing the bulb was a native, having been sent from England to Holland, hence the mistake. It is a misleading name, but it clings to the flower. Always keep these Irises moderately dry; a water-logged, overmoist spot is fatal to a healthy growth, and the best soil is a good vegetable mould, not too light, but of a medium mixture. Sunshine is essential, therefore keep the bulb away from overhanging trees and such like, giving rather a drier position even than the English Iris. A windy situation should be avoided, as the slender stems get damaged. The bulb flower a little earlier than those of the English Iris, and an excellent effect is got when they are associated with dwarf evergreen shrubs. I have seen some delightful contrasts of this kind. Put the bulbs about 3 inches deep, and if they are to be in beds, not less than 6 inches apart. It is interesting to note that the Spanish Iris in particular gives a good account of itself in town gardens, and there is now a large list of varieties, which vary in colour from clouded bronzy yellow to white. The white and pale shades of blue are very beautiful.—C. T.

3670.—Narcissus not flowering.
—With reference to the query about the Double Narcissus, presumably you mean, writing at this late date, the Double Poetious. I may say that the great Daffodil growers have been puzzled by its behaviour, but I think the experience of the largest perhaps of all Daffodil cultivators, Mr. Walker, of Ham, will be of value. It is the same as I have found, and the advice is also the same as I have repeatedly given. It is to grow the bulbs well. Some years ago Mr. Walker's bulbs suffered greatly from blindness, but he discovered that this disease was due to weakness, for if the Double Poetious were permitted to remain more than two years in the same situation, the number of blind flowers increased, but in the first and second year hardly ten per cent. even went blind. This may be cured by good cultivation and annual lifting. You say the bulbs were lifted some years ago, but probably they were returned to the same soil, with the result that the ground was "cick" of Daffodile. You should have selected a fresh site and not permitted the bulbs to again remain years without being lifted. The wonder is that they have made any progress. Lift them once in every year, or at least two years, and therefore lift them now, or as soon as the foliage has died down, and in the early autumn replant them again in freshly prepared soil. I think that next year you will find that the results will be very different from those that you have already experienced. I give a fairly lengthy answer to your query, as several of a similar character have been asked recently. A short time since an article appeared in GARDENING which dealt with this question.—C. T.

3658.—Dandelion on a tennis lawn.
—The best way of destroying these is to pull them up with all the root possible. And to do this effectually, it should be done when the ground is damp and soft. It has been recommended to cut off the tops and drop two or three spots of sulphuric acid on the wound. This kills the upper part of the plant, but the large, long-rooted plants may, and sometimes do, form a new growth at the point where the viticiple ceases to penetrate. The same thing may happen by pulling up the roots—if they break off, and any part of the thick root is left in the ground—but

these are things which are constantly happening, and is a part of the penalty which has to be paid for the neglect which permits a lawn to get full of Dandelions. Perseverance with the weeding tool will get rid of them in time.—E. H.

BOG PLANTS.

GRASS OF PARNASSUS.

This is an extremely interesting and pretty little genus of bog plants, chief amongst which is the subject of the illustration, *Parnassia palustris*, a native of Britain. *P. nubicola* from the Himalayas, *P. fimbriata*, *P. asarifolia*, and *P. caroliniana* from North America, have all larger flowers than our native species, but they rarely, if ever, bloom so freely or do so well under the treatment we usually subject them to in the garden. The American species will exist away from a bog, and I have had them all growing on a western exposure for some years, and they often bloom well. On marshy land or in bogs in the rock garden *P. palustris* is one of the most charming flowers we can at present recall to mind. It is by no means

leaves are elliptic and very fine when the plant is healthy. *P. palustris*, the common Grass of Parnassus (here figured), has white flowers and cordata stem-clasping leaves. It is one of the freest bloomers and, in our opinion, the best of the genus for culture in an ordinary artificial bog. K.

Omphalodee verna.—This should be found in every garden where it can be accommodated with shade and moisture, especially where these conditions exist naturally. It is in such places that it luxuriates, creeping and spreading into the most lovely carpets. I have never seen it so happy as in some of the gardens in the Thames valley district. All gardens, however, do not possess the moisture in which this spring beauty delights; but it may easily be grown in many a cool and shady spot too often barren from year to year.—E.

3676.—Auriculas.—Do not take the offsets from the plants until they have formed roots. If they are intended to be grown in pots, then it will be better to plant them singly, or two or three together in small pots. If for planting out-of-doors flower-pots need not be used at all; they may be planted in boxes or in hand-lights in fine, sandy soil; plant them in firmly, and keep in a moderately moist condition at the roots. Such plants, if intended to flower in pots next season, may be potted up from the ground in September.—J. D. E.

—Do not break off the offshoots until they have had time to produce roots, or you will lose a good many of them. The best plan is to wait until the autumn, then take up the plants, shake away the earth, and divide them as you would a Primrose. You will find that by that time nearly all the offshoots can be separated with roots, and all these will grow into good plants.—A. G. BURTON.

3677.—Pansies, &c., from seed.
—Pansies, Sweet Williams, Wallflowers, and Forget-me-nots are certainly best raised freshly from seed every year, the plants from this year's sowing to flower the next. Any really good things among the Pansies may, however, be perpetuated by means of cuttings. If by Marguerites you mean the Paris Daisies (white and yellow), they are always obtained from cuttings, which should be inserted in the early autumn in a cold frame. The soil being light and sandy, all the subjects mentioned may be safely sown in a well-prepared bed in the open ground. Sow the seed at once, except that of the Pansies, which for spring flowering will be quite forward enough if sown in July or the early part of August. Choose a shady place for this last.—B. C. R.

—If you have good varieties of Pansies, the way, of course, is to propagate these by cuttings, which strike very easily, as it is only necessary to make up a bed of light soil in a frame, and put in the cuttings some time in August and September. Select nice stubby side-shoots with, if possible, a few roots attached, as these go through the winter well, and form good plants. Keep the soil fairly moist, but on no account should it be too wet.

In the following April they can be transferred to the places they are to occupy in the garden. Before doing this expose the plants for a few weeks before as much as possible to air, so as to get them well hardened, but not let them get injured by severe frosts. A cool, moist, naturally shaded position is best for the plants, and in dry weather give plenty of water. In this way you can keep up a stock of good pot plants, and keep them true to name when taking the cuttings. The time to sow seed is the month of July, and sow in shallow pans filled with a light soil, and put them in a cool place. They will soon germinate, and may be pricked out into larger pans or boxes, being in no hurry with the latest to come up, which often provide the finest flowers. In the early autumn put them out in the positions they are to occupy, and they will grow well through the winter. The Sweet Williams are best treated as biennials, although they can be had after two years, but they are a trouble. Always have a good young supply on hand, and nothing can be more beautiful in its way than a mass of the fine double crimson, which is a lovely flower both for its perfect Gothic shape and superb colour. Seed may be sown at once in a well-

OUR READERS' ILLUSTRATIONS: GRASS OF PARNASSUS (*PARNASSIA PALUSTRIS*). ENGRAVED FOR GARDENING ILLUSTRATED FROM A PHOTOGRAPH SENT BY MRS. NEWMAN, HATFIELD, HASTINGS.

an uncommon plant in gardens, and when taken in hand and cultivated it is really surprising to see what a fine effect it gives. The other species noted above, though not so free-flowering, are well worth growing, especially *P. fimbriata* and *P. nubicola*, which are handsome, and if cared for and periodically raised from seed do well and bloom freely the second and third years. We grow them mostly in a moist, sandy peat, and we find this answers well for all the species. They are readily raised from seed, and most of them may be increased by division. *P. asarifolia*, introduced from North America in 1812, is an extremely pretty plant, with Asarum-like leaves and larger flowers than the British species. The flowers are large, white, and produced in summer. *P. caroliniana*, from the North American swamps, has large white flowers, netted with green or purple lines, and when doing well is very effective. *P. fimbriata*, with large, prettily-tinged flowers, is the most beautiful of the North American forms, and is well worth special care. The leaves are curiously hollowed out near the base and look like pedate leaves. *P. nubicola*, introduced a few years ago from the Himalayas, is a fine robust species, with large white or straw-coloured flowers. The

prepared sunny bed, but it is better always to sow earlier than this. As, however, that cannot be done now sow at once, and when the plants are of sufficient size thin them out, so as not to get the growth weakly. In September they may be put into their permanent positions, and the following year they will flower well. Good kinds, worth perpetuating, may be readily increased by cuttings, which should be taken off early in the summer, and placed under a hand-light in a well-prepared soil. Secure all good decided colours, and do not pay too much regard to a dwarf habit. Wallflowers are biennial. Raise the plants from seed in May, and cuttings may be put in when the plants have flowered. Always transplant Wallflowers from the seed-bed, not letting them grow simply on a tap-root, so by this means the production of plenty of fibre is prevented. It is those that are well provided for in this respect that stand the winter satisfactorily, much more so than those with tap-roots. The winter plays havoc often with Wallflowers, but it is sappy, ill-conditioned plants that are the more likely to succumb. A very hardy kind is Belvoir Yellow, which is showy as well. It is necessary to get plenty of young plants of Forget-me-not, which are very easily raised from seed. Sow in the open.—C. T.

—Pansies, Sweet Williams, Forget-me-nots, Wallflowers, and other hardy flowers are much better sown outside in a well-prepared border than in a frame. Young plants, as a rule, are better than old ones, though Wallflowers may be cut back and kept for this second year. Pansies may be increased by cuttings or division.—E. H.

3668. — **Wireworms in a flower-garden.**—There is nothing that will destroy wireworms that will not injure the plants. The best way to get rid of these is to lay baits of Carrots, Potatoes, or French Beans. I have caught dozens of wireworms from a small handful of French Beans just buried in the ground and Carnation bed, marking the spot with a short stick, and overhauling the Beans about twice a week. Carrots and Potatoes are used in the same way.—E. H.

—Wireworms are dreadful pests to have in one's flower-beds, and nothing but patient, painstaking care will get rid of them. These insects are very partial to Carrots when they are buried in the ground. You cannot do better than get some old ones and place them amongst the plants, about 2 inches under the surface. Mark each one with a stick, and examine them once a day, when probably you will find many of your enemies eating their way into the Carrot. You have a tiresome job before you; but there is no other safe and sure remedy.—J. C. C.

—You cannot do better than adopt the old-fashioned plan of getting some small Potatoes and make a hole in them, inserting them just beneath the soil. The wireworm has a strong liking for Potatoes, and the tubers can be lifted at intervals and placed in boiling water to kill the marauders. Look at the traps every day, and you will succeed in getting rid of large numbers. Wireworm-ridden ground is very difficult to deal with, and in the autumn, if this particular spot is much affected, I should remove the plants, particularly if they are Carnations, and give a good dressing of gas-lime, which has been found efficacious. Expose the soil well, and in the case of quite newly acquired ground, on top pasture, for instance, the usual way is to crop it with Potatoes for a time, so as to get it in thorough working order, and get rid of one of the worst pests in garden—wireworms. In your case try Potatoes.—C. T.

3710.—**Hiding eel in a garden.**—In flower-beds I have seen the eel hidden in a well-kept garden by the free use of the many varieties of Boncrop. These plants are not deep-rooted, and when in flower are extremely beautiful. I do not think they rob the ground to any considerable extent, and there is only one objection to them—they help to conceal slugs.—A. O. BUTLER.

3685.—**A Surrey garden.**—One cannot but sympathize with you in some of your troubles; but it is what all who enter upon a gardening career have to contend with. With regard to the Cherry and Apples, you are unnecessarily anxious. Leave the branches alone, and by all means give the roots a good watering twice a week all the time the dry weather lasts. You can make a Minshroom-bed without a frame. It would be best made up in the shade of a wall or building with a north aspect. Mind that the manure is fairly

moist when you use it. With regard to the Roses so recently planted, do not prune them at all now; but by giving frequent root waterings and mulching the surface soil with manure, encourage them to make good growth this summer, which should be allowed to grow in its own way until the end of the autumn, when it may be pegged down close to the ground. Reine Marie Henriette is not a good Rose for pegging down, because of the natural pendent habit of the flowers. I am afraid the Thuja Lobbi plants are past recovery. The turly soil and long drought has caused the mischief. If the plants are dead take them away at once, and devote the present time to preparing the ground so as to get the turf more rotten by the autumn. Fork over the space, say, once a month, breaking any hard lumps to pieces. When the ground is moist the middle of September is not too early to plant such subjects as Thujas, providing the plants have not to make a long railway journey. If you think there is any hope of saving the plants a mulch of Cocoa-nut-fibre will do good, especially if you thoroughly moisten the soil about their roots first.—J. C. C.

ORCHIDS.

MILTONIA CLOWESI.

This is a plant asked about by "Odonto," and he complains at the foliage becoming so very yellow. Now, to admit the truth, it does get very yellow if exposed to a great deal of sunshine; but the kind named here is not so much liable to become tarnished as the forms known as *M. spectabilis* and *M. Morelana*. *M. Clowesi* flowers in the autumn months, even in the months of October and November, so that a good exposure to the light may be given without fading the green from its bulbs or its leaves. It is now considerably more than half a century ago since its flowers were first seen in our gardens; it blossomed first with the gentleman to whom it is dedicated, and it is at once one of the most useful and pleasing species in the genus. It is erect in habit of growth, when strong the bulbs being quite 4 inches in length, oblong, tapering upwards, and bearing a pair of leaves some 18 inches long, which, together with the bulb, are of a bright cheerful green. If allowed to stand fully exposed to the sun, I have seen them become a rich orange-yellow, and this colour does detract from the flowers, these being in the sepals and petals of a rich deep yellow, blotched and marked in a transverse manner with chestnut-brown, the fiddle-shaped lip being white in the apical part, deep violet-purple at the base. One variety of this plant is called *Lamarckiana*, and it is a very desirable form, having larger flowers than the type; the sepals and petals broader, and the lip much larger and less constricted in the middle. There are also one or two other well-marked forms, some having far denser spikes of blooms than others. Now "Odonto" wants to know particulars of how to grow this plant? This is an easy and simple matter, if you have the right amount of warmth for it, for although this Orchid is said to come from the Organ Mountains, in Brazil, it does not reach a great altitude, and it likes to be accorded as much heat as *Cattleya Mossia*, and it likes to be hung up best; so if you have this plant in a pot it is best suspended in a position where it gets full light, but so as it can be shaded from the burning influence of the sun. Drain the pots well, because when growing they require a large amount of water to their roots, which should have ample means of getting away quickly. A nice damp atmosphere is also requisite. When the plant is coming into flower it may be removed from the reel and be stood upon the stage, when, if care is taken, the flowers will maintain their gaily until near the end of the year; in fact, I have had the plant in flower at Christmas, and the flowers still in quite a fit state to be presentable on the table at this time. MATT. BRAMBLE.

AERIDES CRISPUM.

I AM in receipt of a nice spray of flowers of the above-named plant from "Mamo," saying he has a plant with three spikes, and he says I might say a word about the various members of the genus? Well, I have been somewhat long in

my remarks upon the various species of *Aerides*, perhaps because I have always considered them out of the usual run of plants which my readers dabbled in, but seeing that there is no telling what sorts you really do take up with, I must extend my radius somewhat so as to include some of the East Indian kinds. Now I am very glad to find there is some of the old love for these *Aerides* still to be found amongst growers, for they, in company with *Vandas*, are still amongst the most beautiful of orchidaceous plants, and since it has been proved that 60 degs. in winter is quite hot enough for them, saving a few species which require some 5 degs. more heat to carry them safely through the winter months, anyone having a stovehouse may grow them, for they will thrive along with a mixed assortment of stove plants even better than the majority of Orchids. They are erect and upright in growth, and thus the plants maintain themselves amongst the various plants in a stove, and do not become smothered up and buried beneath the foliage of the surroundings; and *A. crispum* is one of the very best for this, as also are the varieties *A. crispum Warneri* and *A. crispum Lindleyanum*; and these would appear to constitute a section of the genus noted for having the erect stems, of a blackish-violet, and somewhat broad and short leaves. They have long spikes of bloom, which are frequently branched, bearing numerous, very large, fragrant flowers, rosy-purple and white, and which last in perfection a very long time. Now this plant and its variety, *Lindleyanum*, are mixed in a great measure; but the usual difference lies in the typical plant having a racemose inflorescence, or with simply a short branch or two at the base; but the variety has long branches, and the flowers are larger and brighter in colour, whilst *Warneri* is so thoroughly distinct that no one can mistake it, the growth being slender, and the leaves set in an ascending manner, and the racemes set with numerous slightly smaller flowers. *Crispum* and its variety *Lindleyanum* are both found in the Neighbourly Hills, as I have frequently been told by my friends who have been there; but I have no idea whence the plant called *Warneri* comes. This, perhaps, is from a warmer spot in this vast country, and my inference is drawn from observing that it likes a slightly hotter place in the winter months. They should be potted in sweet Sphagnum Moss alone, the drainage good, and be treated to a good moist atmosphere. MATT. BRAMBLE.

3672.—**Zygopetalum Mackayi.**—This is a good old Orchid and well known to cultivators. It is not difficult to grow well. I find the plants do best in the Cattleya-house and must be kept shaded from bright sunshine. The plant requires a good-sized flower-pot, and should be planted in good fibrous peat and some Sphagnum added to it. The pots must also be well drained. All the bulbs do not make growths; the leading bulbs only do this, and they usually make but one in a season. They flower in the winter, the flowers being produced on strong upright spikes, and last a very long time in good condition; some varieties produce much more beautiful flowers than others. The flowers have yellowish green sepals and petals, marked with purplish-brown, the lip is white, beautifully marked with blue lines and spots.—J. D. E.

3679.—**Ceologyne cristata.**—It is not necessary to repot this Orchid annually; it may be repotted every second year. Small plants may be repotted annually. They do not like too much sunshine upon them when making their growth, but should be placed near the glass roof. I usually place them on the north side of the house. It is found that they do better with some fibrous yellow loam mixed with the Orchid peat. It is not usual for the plants to produce a second set of flowers after the first have faded and been cut off. The plant starts into active growth immediately after flowering, and these growths will, of course, in time form new bulbs. They should be repotted just before this growth begins; if done when the growth is so far advanced as it is now, the plants would doubtless experience a considerable check.—J. D. E.

3612.—**Lime-water and worms.**—The lime-water should be clear, and drawn off from the sediment. It is a very harmless remedy, and may be applied to most plants without any injurious results.—O. T.

HOUSE & WINDOW GARDENING.

THE DUTCHMAN'S PIPE (ARISTOLOCHIA SIPHO).

It is a pity that this, one of the handsomest climbers we possess, should be so little known or appreciated in this country. Its beauty consists in the large, heart-shaped, bright-green leaves, which measure, under favourable circumstances, as much as 7 inches in diameter. The plant is common in North Germany, and is perfectly hardy; it will grow under any aspect and in any fair soil. The specimen shown in the photograph is trained up the side of a house, ever and among the underlying Ivy. As the Aristolochia does not attach itself to walls, it is best to train it on trellis or wire-netting, and it

plants may be stood upon a bed of coal-ashes in a shady part of the garden, but must not be allowed to suffer from want of water. The best time to pot them, if this operation is required, is when growth is being made, and, as a rule, early in July is a good period for this work. The soil should be composed principally of peat, and this should be of good quality, otherwise the plants will not thrive well. The reason of this is that the annual repotting is not necessary, as in the case of many soft-wooded things. The plants should be repotted into pots 2 inches larger, and the soil made quite firm, using for the purpose a potting-stick, as if it is at all loose good growth will not be made. The pots must be thoroughly well drained. Put in plenty of crooks, one or two large ones in the bottom of the pots, and over them the smaller

are so largely sold in our streets during early spring for room decoration. Very beautiful they are, and their sad fate is, too often, to die away rapidly from the combined effects of gas and want of water. But, with care, they may be reserved from year to year, without any artificial heat, if a small greenhouse, or even a spare bedroom or bathroom, net lighted with gas, can be used for them. The first thing to be done, as they go out of bloom, is to pick off each flower as it fades; this is an invariable rule with all blossoms, for seed-bearing exhausts a plant much more than blooming, and few flowers can be expected next year on any plant which is allowed to go to seed. Ericas make their fresh growths directly after they blossom, and should be kept as warm and moist as possible at the time they do this; in fact, this is the only season of the year in which they will bear moist fire heat without injury to their constitutions. Directly after flowering, then, they should be removed to the greenhouse, and allowed to stand on damp ashes, or damp stones, to give the moist atmosphere they need at this time, as well as a thorough supply of water. It is an invariable rule with all Ericas that they must never at any time become dust dry, or their fine hair-like roots will perish, and the plant will probably die, or become a miserable object. Growing in peat as they do, they should have plenty of water given them at a time, so as to thoroughly saturate the whole hard ball, and if the plant should be in a very small pot, it is well to give it a slight shift directly it has bloomed, to give room for the formation of healthy roots. In pottling, the ball of soil must not be broken, only the drainage removed, and thorough drainage arranged in the new pot, which must only be slightly larger than the first. Having covered the drainage with the rougher parts of the peat, and this with a little fine soil and sand, place the ball of roots in the new pot (which must be well scrubbed inside and out and dried before using) and ram down all round the plant some compost composed of fine peat and silver sand. Great firmness is necessary in potting Heaths (or their delicate roots will not be able to grasp the new soil), and a space of at least three quarters of an inch should be left empty at the top, to hold the necessary water, the surface being made firm and even. Having been watered, and placed in a warm, close atmosphere, the Erica should be left alone, and not watered again until the surface soil is dry enough not to soil the finger, for overwatering before the roots have had time to grasp the new soil will be likely to rot them. When the new shoots have become pretty firm, and are no longer growing rapidly, the plant should be placed out of doors, in a shady spot, standing on damp ashes, and kept regularly watered throughout the summer. At the end of September (or before in a cold season) the Erica should be placed again in a greenhouse, or a bay window, from which frost is excluded; there it will form buds, and flower in the spring. If no greenhouse be available, a tolerable substitute for the moist air of a greenhouse may be made by covering a large old tray or flat bath with Cocoa-nut-fibre or Moss, which should be constantly kept damp, and standing the plants on the moist bed, without, however, allowing them to be in water. This arrangement in a bath-room window can be well carried out, but in severe frost Ericas should be placed at a distance from the window, in a warm bedroom, no gas being burned in it.—J. L. R.

Dutchman's Pipe (Aristolochia Siphon) and Ivy on a house wall.

is, therefore, particularly suitable for covering verandahs or summer-houses. As an extremely handsome, hardy, quick-growing plant, of the easiest cultivation, it certainly merits more general attention than it receives. The flower is inconspicuous, appears in early summer, and has a fanciful resemblance to the hawl of a German pipe on a short bent stem. Hence it is bracketed in the catalogues as the "Dutchman's Pipe." The Germans call it the "Pfeifenstrauch." It is deciduous.

3604.—Ericas after flowering.—Carefully remove all faded flowers, taking especial care not to pull out the young shoots, and return the plants to the pit or house from whence they came. Keep them well watered, as upon this point depends their successful cultivation. When the summer approaches hard-wooded

ones, so that the soil cannot well get water legged. After the crooks put a little of the rougher parts of the peat, and mixed with the peat should be a fair portion of sharp silver sand. Before repotting take care that the soil is not dry, and if this is the case it must be made thoroughly moist by soaking it in a pailful of water. After repotting put the plants in a frame and stand them on a layer of coal-ashes to prevent worms entering the bottom of the pots and disturbing the drainage. Give water also cautiously after watering. During the summer it is of the utmost importance not to allow the plants to get dry. If they remain so for any length of time they seldom recover properly, and they should not be exposed if the summer is wet and cold, as it sometimes is.—J. L. R.

Probably this query refers to an Erica hyemalis, or one of the other varieties which

3631.—Climbing Roses, &c., for a house-wall.—Bonveirde is Malmaison is not a climbing Rose, although worth growing for its exquisite blossoms, which are borne earlier and later than most other Roses, often opening in November during a mild season, and again in May. Few climbing Roses would do well in a north-east aspect, except that most useful Rose Oloire de Dijon, which can be well grown at any point of the compass. Others, such as Hemera, and the sweet old China Monthly Rose, may do, if the situation be not too much exposed to the winds of winter, but if so, it would be wiser to substitute other creepers, such as Ampelopsis Veitchi, with magnificent autumn foliage of every hue; Clematis montana, with white starry blossoms, borne in the greatest profusion in spring; Yellow Jasmine, and others. Thorough preparation of soil with old manure dug in, and careful planting, are essential to the well-being of all creepers.—J. L. R.

INDOOR PLANTS.

3607.—**Treatment of Palms.**—As regards pots for Palms, both the stronger and more weakly growing kinds will succeed with lesser root space than the majority of pot plants. If, however, you wish to get specimens, then more liberal treatment may be advised when the plants are young. A very good time for potting Palms is the present, and for such kinds as *Cocos Weddelliana*, pots two sizes larger will be quite sufficient for the plants, and the best soil to use is a good yellow loam; but in loam of ordinary character they will succeed well, and to the compost should be added a fair portion of silver-sand. Drain the pots by putting in the bottom a few crocks, and make the compost firm, as Palms, like *Ericas* and hard-wooded plants generally, do not like loose soil. Such Palms as *Chamaerops humilis*, *C. Fortunei*, *Lantana horbortica*, *Rhaphis flabelliformis*, etc., do not require a high temperature; a greenhouse will suffice for their growth. If they are not wanted of very large size in future pottings a good plan is to take the plants out of the pots, and after removing some of the old ball carefully return them again to the same size. The pots must, of course, be well cleaned and dried before again being used. After repotting keep a warm temperature maintained to assist them to get established quickly and syringing freely. Water cautiously at first, but afterwards more liberal supplies may be given. During the summer months it is important to give shade, as when the sun shines full upon the foliage it gets scorched, and the beauty of the plants is thus destroyed. This is a very good time to purchase a few good healthy plants to commence with. Remember also that if the plants are used in rooms or such places the foliage must be kept continually sponged, to prevent accumulations of dust, which are very hurtful.—C. T.

—“Jane” does not say whether or not these Palms are used for room decoration, but if so they will require more care than in an ordinary conservatory, where most Palms will do well, if regularly watered, and allowed a warm temperature. Palms in dwelling-rooms should be sponged every week, for the dust soon accumulates on their broad leaves, and interferes with their health. Great care is also necessary with regard to watering Palms, which should never at any season of the year be allowed to become dry, but they need a great deal more water during the summer, when they make their growth, than they do in the winter season. The best rule is to place the finger on the top of the soil when in doubt, and supply water only when this is dry enough to leave no stain on the skin. But when water is given it must be supplied in sufficient quantities to run through the pot, the saucer in which it stands being emptied an hour after watering, for the plants must on no account stand in water. Potting may be done best in spring, but Palms do not often need potting, and are best in small pots for this size. They should have a mixture of two parts pot to one of leaf-mould, with plenty of silver sand, which should be tightly rammed round the ball of roots without disturbing them, except to remove the drainage. Palms need excellent drainage; this should be carefully arranged as follows: Cover the hole of the pot with a piece of rock, the concave side downwards, and place over this several smaller bits, so as to keep a clear egress for water. The crocks should be covered with a bit of Moss dipped in soot, to keep insects out, and then with the rougher parts of the peat, reserving the finer soil for the upper part, and pressing this firmly home with a blunt potting-stick. Enough room should be left at the top for watering purposes, and all made firm and smooth with a sprinkling of silver sand to finish, as this helps to prevent the pot from “greening”—i.e., becoming mossy and sour. Palms when repotted require damp heat for a time to enable them to make fresh roots. If a conservatory be not available the plants should be sent to a horticulturist’s for two or three months, and then carefully hardened to the open air, which is not difficult in July or August. They will do well for years in a sitting-room, if once well established and regularly cared for, even standing (at least some of them) a little occasional gas, which usually is fatal to plants

life. Soot-water in a thin state will help to support them if in rather small pots, but it should not be given unless the plants are in full growth, and then not more than twice a week at the outside.—J. L. R.

3627.—**Cyclamen culture.**—It is a bad practice to put the tubs in the open air. They should be kept indoors till the foliage dies off, watering them carefully. When the leaves die allow them to remain for a fortnight without water, then shake away all the old soil, and re-pot in a nice free compost of two parts fibrous loam and one part leaf-soil, with a liberal addition of white sand. Water only when the soil is quite dry till the young leaves appear, and then more freely. Plenty of flower-buds will then form during the autumn months. You may certainly use a little bone-dust in the compost.—J. C. B.

3606.—**Hydrangeas for market.**—The common *H. noronensis* and *pauciflora grandiflora* are most largely grown for the London markets. The latter has become very popular during the last few years, and when really well grown makes good prices during the latter part of May and through June. *H. hortensis* can be had in bloom a month earlier, and with high culture produces enormous heads of bloom in 6-inch pots. The white variety, Dr. Hogg, is also grown to a considerable extent. Cuttings strike freely in cold frames if they are taken just as the wood matures. To obtain large heads of bloom, the cuttings should be inserted singly in small pots, shifting them at the turn of the year into 5-inch pots, using good loam, with a liberal addition of rotted dung or some concentrated stimulant. Liquid-manure must be given freely as soon as the flower-trusses form. *H. paniculata* requires a longer period to bring to good marketable size. The young plants are best in the open air through the summer, pruning them in hard, and putting them into their blooming pots in January. For early bloom constant warmth is, of course, required.—J. C., *Byfleet*.

3667.—**Malmaison Carnations.**—These are easily grown and soon form large specimens if they are treated as greenhouse plants. I had one plant only die this year, and have no doubt that its death was owing to careless watering. A plant may get over-dry and the fine, delicate tips of the roots perish. The gardener observes his plant in distress, and finding it is caused by dryness at the roots, he pours water into it freely, with the result that the plant cannot take up the water, and instead of holding back from the free use of the water-pot, more and more is given, the roots perish altogether, and the plant dies outright. This, I know, is the cause of the death of some Malmaisons; others are killed by a wireworm getting to the part of the stem underground. The plants like good rich potting-soil, composed of four parts good fibrous yellow loam, one part leaf-mould, and one part decayed manure with a portion of coarse white sand. Some persons overpot their plants; this is a grave error, and if not carefully watered after may be the cause of the death of some. Water the plants when they really need it, and this can be ascertained by tapping the sides of the flower-pots with the knuckles of one hand, using the water-pot with the other. Do not give manure-water to any plants until it is seen that they have filled their pots well with roots.—J. D. E.

—Very likely a wireworm had found its way into the pot, or the egg may have been in the soil when the plant was potted. These plants also occasionally collapse in the way described if overwatered, and as it was so full of buds, very likely it may have had a little too much sometimes. These, and indeed all Carnations, when grown in pots, should never have any water given them as long as the soil remains even slightly moist. The drainage ought also to be free, and the soil—a sandy loam is best—be compressed quite firmly in the pots. If any of these points are neglected the plants are very liable to become water-logged at the root, and then death is certain to ensue sooner or later.—B. C. R.

—These are far more difficult to grow well than many suppose, but it is worth trying to get good flowers, as they are very popular. I will give you a brief code of treatment followed in gardens. The flowering-time of the plants is April and May, and when finished blooming, the

usual course is to plant them out in the open, as this promotes a well-ripened growth. Layering is done as for the ordinary kinds. When the layers are rooted, which is in September, they are potted, 5-inch pots being the size used. A good loamy soil will form the best compost, and it should be mixed with a fair proportion of sharp silver-sand, also some charcoal to keep it sweet and open. Meanwhile, prepare a site for them in the open, laying down a layer of coal-sashes on the surface to prevent worms getting into the bottom of the pots and disturbing the drainage. Water thoroughly, and in the month of November remove them indoors, and another shift into 7-inch pots is given. During the winter months the plants must not be coddled in any way, but given abundance of air, and the soil only just kept sufficiently moist. Too much moisture is fatal. The plants may be grown also as perpetual-flowering Carnations are treated. I do not know your accommodation, but this will doubtless be the better plan for you. The general treatment is similar. Always keep the plants cool, hardy, and water cautiously. It is doubtless through too much water that your plant has behaved in the way described.—C. T.

Watering indoor plants with cold water.—In page 15, Vol. IX., of *GARDENING*, there is an article by a correspondent, “B,” under the above heading, where he brings fact and argument to prove that “undue importance has been attached to watering tender plants under glass with water of the same temperature as that in which the plants have been grown.” He mentions the case of a large house, filled with tender tropical plants “in admirable condition,” where for ten years there had been no other means of watering than with water contained in a large tank with no protection from the weather, a considerable amount of water being required, even in winter, when the tank was often covered with ice. He also remarks: “If cold water exercised a very injurious effect on the roots and foliage of tender plants—as it is often supposed it does if plentifully used—there would be certainly an end to Cucumber-growing in many of the London market gardens, where the only water obtainable is taken cold from the tap.” For some years I have used almost exclusively cold water to Cucumbers in house, pit, and frame with satisfactory results. At the present time I have Cucumbers in a hot-bed, growing luxuriantly, that are watered and syringed wholly with cold water from the tap. It is my opinion that where all the warm water for watering and syringing has to be taken from the kitchen boiler, and where a full supply cannot always be obtained (the water being required for kitchen and other household purposes), the fear of using cold water for the purpose is often indirectly the cause of red-spider.—L. C. K.

3657.—**Celsia oretica.**—You should be able to get seed of this plant at any good nursery, as it is not uncommon now, although at one time was little seen. The *Celsia* is a near relative of the *Mulleins*, and is not hardy, although as an annual it may be made excellent use of in the flower garden during the summer months. When thus to be grown, the seed must be sown early in the year in gentle heat, and grown on as for half-hardy annuals in general, being when ready to go out good-sized, robust examples. If you require the plants for the enrichment of the greenhouse—and it is excellent for this purpose—the best way is to sow seed now, and get the plants out for the best part of the summer, if possible, and pot them up in the autumn. It is not necessary to force them at all, and the plants when in full bloom are very ornamental, the flowers, rich-yellow, produced freely, and making a fine show. It is a pity one does not see the *Celsia* more in small gardens.—C. T.

—Apply to Mr. W. Thompson, 32, Tavern-street, Ipswich.—A. H.

—I do not know where seed of this plant is to be had, but if “B.” likes to send me his address, under cover to the Editor, I can put him in the way of obtaining young plants of this apparently rare but charming subject.—B. C. R.

3690.—**Treatment of an Oleander.**—It will tend to make the plant bushy at the point of the shoot if picked out early in the year. Tidy loam, two-thirds, one-third leaf-mould, with sand enough to make it fairly porous, will grow Oleanders well. The plants require a good deal of water at times, so the drainage must be right.—E. H.

NEGLECTED GREENHOUSE PLANTS.

LUCULLIA GRATISSIMA.

The limited extent to which the cultivation of this handsome flowering shrub (here figured) has attained since its introduction some seventy years ago would lead one to the conclusion that it does not merit any particular notice by lovers of the very few really good plants that are to be seen in gardens. Such, however, is far from being the case, for wherever the culture of temperate-house plants is attempted, there the *Lucullia* should find a congenial home. It may be grown in a greenhouse which accommodates the majority of plants coming under that designation, but it is not so much at home in such a house. A house which is suited to *Camellias*, and where the surroundings are such as to be conducive to a healthy and vigorous growth in the case of these plants, is also calculated to suit the *Lucullia* remarkably well. This may to some seem strange when a temperate-house has been more particularly recommended, but it must be borne in mind that when *Camellias* are making their growth they delight in a fair amount of warmth and plenty of moisture. If the *Lucullia* is given such a house it should be placed in a position where not liable to suffer from sharp currents of air, nor should it be too much exposed to the sun's rays during the middle of the day. A conservatory wherein the majority of the plants are growing in beds rather than in pots or tubs will be an excellent place for it. If a space of wall has to be covered where it is possible to plant the *Lucullia* out without the opposite extreme of too much soil, there it may be grown with every prospect of success. It is more adapted for growing in beds and borders than in pots, yet, as indicated in a previous sentence, the opposite extreme must be avoided, otherwise there will be a tendency to make rank wood, which will be unproductive of bloom. A regular soil, it does better in peat than in loam. Light loam will suit, but any tendency to a heavy retentive soil should be avoided at all times. Light fibrous loam and peat of good durable character in equal parts, with the addition of coarse silver or river sand, would make a capital mixture for it; lime rubble and charcoal would likewise be good additions. The pruning should be seen to after flowering; some in most instances will be found necessary; it thrives well when pruned rather hard, but I would prefer a more moderate course. Before pruning it is a safe plan to let the plant get dry at the root to prevent exhaustion by its bleeding. The stronger shoots should be stopped so as to regulate the growth before they become too much advanced. P.

Flowering-shoot of *Lucullia gratissima*.

bloom. A few weeks previously it will have been possible to grow them out-of-doors (or at least in a frame with the lights on at night) in the case of the Ten-week varieties, whilst the East Lothian forms will, of course, have a long period in the open before they flower.

MIGNONETTE SEED of such approved kinds as the French variety Machet, Miles' Spiral, Crimson King, Dwarf Erect, and Oaraway's White, if sown now will provide a most useful lot of plants that will come into flower before the outdoor stock, and in succession to the autumn-sown stock. Mignonette-seeds should always be sown in the pots in which the plants will afterwards flower when the growing of a serviceable decorative stock is the primary object in view. Repotting into larger pots only involves unnecessary labour, absorbing time which might be more profitably devoted to other things. It is, of course, essential to give shifts when growing larger plants as standards or as extra-sized bushes. For most practical purposes what are termed 48's and 32's will be found the best sizes to use; smaller pots involve more labour in watering, larger ones give too much soil, with a disposition on the part of the plants to die off when the soil is overmoist and the seedlings not arrived at a good size. The soil should be oblique loam, the best being that which is of a friable nature, neither too heavy nor too light; and from heavy some leaf-mould should be added. This soil should, if possible, have some

lime rubble that has been powdered down fairly fine mixed with it, and that in place of sand; it should also be quite on the dry side. I do not mean absolutely dry, the object being to ram it as firmly in the pots as when potting pot Strawberries or Cape Heaths. The object of this is to secure a more enduring growth; in loose soil the plants grow too rank, whilst the same condition will tend to a greater retention of moisture for a longer period than is desirable. The pots should be well cracked; then a layer of fowl's manure, if available, should be added before the soil, not mixed with it, for the simple reason that this stimulating agent is not needed until the plants are well advanced. With a firm surface the seed should be sown, and a little fine soil added in the same manner; no heat should be employed to raise the plants, a cold pit or frame being the best place. The surface may be advantageously screened by means of sheets of paper until the seedlings are above the soil; then all the light possible should be given. When large enough to see which are the most promising plants, the weaker ones should be thinned out, so as to leave from five to seven of the best to each pot. Until well established, a moderate supply only of water is needed, but when it is seen that the plants are making good headway, then more is required. Mignonette should never be allowed to suffer for want of water, more particularly when the pots are filled with roots. If allowed to get dry a few times, the older foliage will soon fade to a brownish colour and tell its own tale. As an additional stimulating agent, I have not yet found anything to surpass weak Peruvian guano-water; this will fulfil all the requirements. The best plants in my case have been grown upon light shelves near the glass. True, they take a lot of water, but without painstaking no one deserves to succeed. When in full bloom the plants can, of course, be placed where desirable, but the seed-pods should be removed, so as not to distress the plants. There are several varieties of annual

GRASSES, such as are termed ornamental, which are well worthy of extended cultivation in pots. Of these the following may be recommended as amongst the best: *Agrostis nebulosa*, *A. laxifolia*, and *A. pulchella* (the last making the most compact plants). *Briza gracilis* is the most suitable for pots of its class. *B. maxima*, although a beautiful kind in the open border, is not so well suited for this work. *Eragrostis -legans* as a later kind to come into use is especially good. This Grass is best sown in the open ground, being lifted when of good size for potting, but not sufficiently advanced to cause any check to the growth; the pots should then be replunged in the open ground, looking to the watering as may be desirable. *Hordeum jubatum*, although a tall-growing kind, is well worth attention, and so is *Lagurus ovatus* (the Hare's-tail Grass). These are all varieties that are ornamental in a flowering state, but for its value as being ornamental in its leaf-development, *Eulalia japonica zehra* should be named; its use would save many plants of enduring growth from being run upon too much in decorative work. A fairly light soil will suit all of these Grasses, the same-sized pot as recommended for Mignonette being advised, and with the one exception named above it is best to sow the seed and not afterwards disturb the young plants, that of the *Eulalia* being sown quite thinly. A very pretty plant of dwarf growth is

ASPERULA AZUREA SETOSA, a species of Wood-ruff. Although it is not a showy kind, it is extremely pleasing when in flower; it does not require any special cultivation. For flowering during the summer months the *Calliopsis* are well known in the open border, but they are quite as useful in pots when a fair amount of pains is taken in their culture. The seed may be sown in the open or in pots. I prefer the latter method, a shift being given once when the plants are so near to need it, some little time before coming into flower. Having arrived at this latter condition, they should be brought under cover and kept freely watered; a light position will suit them best. Of the *Campanulas*, the quick-growing *C. Lorei* should not be passed over. A few seeds of this small Bellflower may very well be sown in the pots with the *Geranium* previously alluded to; this makes a very pretty mixture. *Centaurus* furnish us with the *Coronilla*, which will

ANNUALS FOR POT CULTURE.

WHERE the room is all too limited for the proper cultivation of permanent plants, whether soft-wooded or such as are of hardy and enduring growth, more dependence should be placed upon annuals for purposes of decoration during the spring, summer, and autumn months, more particularly the two last named seasons of the year. For the early spring-time the seed would have to be sown the previous autumn, frame protection being provided during the winter months. Annuals for pot culture must be divided into three heads—viz., hardy, half-hardy, and tender. Of the first named there is a good number of kinds that are particularly well adapted to the purposes in view, and which if sown at once will give a good return in the shortest possible space of time. Some of the best of these are the following: Ten-week Stocks in various colours. In the case of these I have myself kept to the large-flowering scarlet, purple, and white varieties; these are very reliable and afford for all practical purposes three as distinct colours as one could desire. The habit, too, of this strain is excellent for pot culture. For later flowering the East Lothian strain of Intermediates in their distinct shades of

make most fitting companions for the Calliopsis, requiring likewise a generous course of treatment. Should the plants in either instance be found to grow too tall for the particular purpose in view, it will be well upon the second attempt to pinch them before too far advanced. Hibiscus africanus, with its large, sulphur-coloured blossoms, is quite distinct, and is to be recommended where there is a good variety of flower required with a large space to be filled during the summer months. *Linnæa grandiflora coccineum* is a very free growing annual in the open border, being also for pots a very distinct addition; it requires all the light possible when taken under glass.

NEMOPHILA INSIGNIS is an annual that is rarely seen in pots, yet for this system of culture it is admirably suited. It is beautiful when used in margins of stages in the greenhouse or conservatory during the summer. This *Nemophila* may be transplanted from the open border when small; if wanted earlier it would be better to sow in pots and raise in a cold frame. When kept well supplied with water after having filled the pots with roots, it will last a long time in beauty. The most approved varieties of *Asters* hardly require any recommendation, being so well known to many growers, and by many grown in pots for autumn decoration. Grown in pots is perhaps not a correct term, as in most cases the plants are pricked out in the open ground as with other *Asters* to flower outside, being lifted just as they show for bloom. Between that time and the period of blooming there is a long enough interval for them to become well established. The best results are obtained by adopting a hardy course of culture so as to secure dwarf sturdy plants when lifted for potting; it is better therefore to grow the plants in as open a position as possible. The following are half-a-dozen good kinds for growing in pots: *Diadem*, *Veitch's Empress* (both crimson and white varieties)—one of the very best—*Triumph*, *Snowball*, dwarf *Chrysanthemum*-flowered, and dwarf *German*. With such a selection it will be possible to have a long season of bloom, for it will be a rare occurrence to find all of these various strains in flower at one time. Sweet Peas in pots are somewhat of a novelty, yet they can be grown most successfully in pots, but better still in long boxes such as are used in windows. The best success with these fragrant flowers I have noticed in the case of a grower of known repute has been, when sowing the seed in August, the plants were kept in a cool-house all the winter, steadily growing meanwhile and flowering profusely in March and April, when such flowers would be a most agreeable and welcome addition to the cut-flower supply. The plants as they increased in height were trained up the side of a span-roofed house next the glass, producing a very pretty effect, whilst but little room was taken up by the boxes. Well-grown plants of hardy annuals in pots will give a good return for the labour expended, whilst the details of culture are such that anyone may grasp them, finding out for himself, after a few experiments, what in their particular case gives the best results and renders the most service during any particular period. The great advantage in growing such plants is that of being able to throw them away as soon as they fade; thus it is possible oftentimes to retain them in positions where it would not be deemed advisable to allow plants of permanent growth to remain. To those who have to make a good show in their houses with the minimum amount of room for growing and storing plants, I strongly advise recourse being had to these beautiful plants. P.

3624. — Bulbs from Cape Town.—Taking the plants in the order on the list, first we have the *Belladonna Lilies* (*Amaryllis Belladonna*), which will flower well in the open, but, as a rule, do much better in a greenhouse. As you require, however, to know only what will succeed out-of-doors, you may plant the bulbs in a border facing south, and the soil must be good and deep loam; leaf-mould, with sufficient sharp silver sand to make it pliable and fairly light, being the most suitable. It is such a position as this they do well in the Royal Gardens, Kew, where the bulbs flower each year with great freedom, making a great show of colour. This border of *Belladonna* is a picture of colour, the

dark-chocolate stems and bold rosy flowers making a fine effect. You may plant the bulbs now, and if to be grown in pots, put one bulb in each, using a good loamy compost for soil. It is interesting to know that *Dean Herbert*, whose work amongst the *Amaryllids* is famous, grew his *Belladonna Lilies* in a similar position to that described. The *Freesias* should be grown in pots in the greenhouse. The *Watsonia marginata* requires similar culture to the *Gladiolus*, and the genus is very interesting. The flowers of the kind mentioned are delicate rose, and there are several other kinds worthy of mention, as *W. angustifolia* (light-pink), *Mariana* (purple-crimson), *W. speciosa* (crimson), and *Louis XIV* (rose), besides many others. The *Watsonias* are quite hardy; but they are not very often seen in gardens. They are natives of the Cape, and the bulbs should be planted in warm situations and light soil. Give them similar treatment to that required by the early-flowering *Gladioli*. *W. alba* has white flowers, and is a very beautiful plant. The same remarks apply pretty much to the *Ixias*. They must have warmth, but you can try them in the open, putting them in a well-drained position, the soil light, and, if possible, against a hot-house wall, facing south, as mentioned in the case of the *Belladonna Lily*. *Babiana* may be treated in the same way.—C. T.

THE KITCHEN GARDEN.

BRUSSELS SPROUTS.

DURING the last twenty years a number of varieties of this hardy and highly-esteemed

Old Tall Brussels Sprouts.

vegetable have been raised. However much may have been gained in size, it is questionable if we have made much (if any) progress as regards quality. For a long time past it has appeared to me that the Brussels Sprouts of my youth were much superior in flavour and appearance when cooked than those that come to my table at the present time. The sprouts furnished by the newer vigorous-growing strains have a more Cabbage-like taste, and the larger they are the more they lack the true old Brussels Sprouts flavour. The striving after mere size in vegetables is a great mistake, for no increase in this way will compensate for loss of quality. When the Aigharth Brussels Sprouts became so popular some years ago I was charmed with the wonderfully vigorous growth they made. I put them on ground that had been trenched 2 feet deep, and they made stems 3 feet in height with immense foliage, and the sprouts were double the size of any I had ever previously grown. The members of my household, however, unanimously condemned their flavour, and from that time I have never cultivated the Aigharth. I fancy that many were disappointed with this giant kind, for it soon lost the

popularity which its great vigour and productiveness apparently warranted. For some time I have been trying various newer varieties, all of which seem to have gained in vigour at the expense of quality, with the exception of one that I have grown for the last two years. This is grown largely in the Midland and Northern counties. The sprouts are said to make higher prices in the northern market than those of any other kind. Although I gave the plants good ground which had been deeply trenched, they did not run up to so great a height as most varieties do, and the leaf-development was not so exuberant. The yield of sprouts was, however, very large, and what is even more to the purpose, their flavour left little to be desired. The old Tall Brussels Sprouts (here figured) is now not often seen in our gardens, but it produces rather small sprouts of very excellent flavour indeed, and it is hardy and continues to bear for several months. B.

A good Rhubarb.—Rhubarb is now plentiful in gardens, but the kinds grown are generally those with big, coarse stalks, which have not half the flavour of the smaller-growing varieties, such as *Hawke's Champagne*. I notice this excellent variety, and it is one that should be grown by all who put juiciness, flavour, and first-rate quality before quantity. Of course, there is much more in the big-stalked Rhubarb, but such a kind as *Hawke's Champagne* is delicious. The stalks are thin, but deep-crimson, and yield rich juice. It is the finest kind for flavour without question in cultivation, and grows well in good garden soil. One seldom or never sees it at exhibition, as such varieties are not of much account there. Everything is sacrificed for rare size.—C. T.

3661.—Wire-netting for Peas.—Yes; this forms a fairly good substitute for the usual sticks, but the mesh must be large—3 inches or 4 inches. A better and cheaper plan—at least, to my idea—is, however, to run some ordinary twine to and fro along each side of the rows, about 6 inches apart, taking a half hitch round each stake. For a tall Pea, like *Duke of Albany*, you would, of course, require two 3-foot widths of the netting on each side the row.—B. C. R.

—Wire Pea hurdles are especially made for supporting Peas, and if taken care of they will last a long time; or ordinary large-meshed wire-netting will do, fixed to stakes in the ground. This will be cheaper than Pea hurdles, but not be quite so convenient.—E. H.

3671.—Good King Henry and Salsafy.—If the seed germinates and the young plants do well, they ought to be nice little stuff by the autumn, just right for moving; and if replanted, say in October, will begin to be productive the following spring. The roots of Salsafy may be lifted and stored in sand, like Carrots, in October for winter use, though I always think they keep better in the ground.—B. C. R.

—If the seeds of Good King Henry grow, the young plants will move safely anywhere in autumn. Salsafy may be lifted in October, and laid in elsewhere till required for use. Frost does not injure Salsafy, and if laid in a trench it will keep quite fresh till required for use.—E. H.

3684.—Best Melon and Vegetable Marrow.—Melons cannot be grown in the open ground in this country. The fruit would be flavourless in the average summer. Little Heath, a hardy scarlet-fleshed variety, will do under glass with a bed of fermenting materials to start it if the summer is a warm one; but I suppose scarcely anyone who knows what the flavour of a good Melon is would call the Little Heath when grown cool first-class. As regards Vegetable Marrows none cannot go far wrong. The Long White and Long Green are excellent when cut young. Hibberd's Prolific is much smaller, but in all other respects it is excellent, and is, perhaps, better adapted for a small garden than the larger-fruited kinds.—E. H.

Looks and their culture.—To have these large and fine they require a long season's growth, and must, therefore, be sown early to get the plants forward and strong before planting them out. A good way of managing with them is to fill a shallow box or pan with fine rich soil and sow the seed therein, placing it in some warm-house, pit, or frame to get it to germinate. As soon as the plants are large enough to handle, they should be pricked off or potted singly into small pots and be nursed on under glass till they are big enough and the weather is favourable for turning them out. To get ready for

this, one method, and that the best, in to form and dig out trenches 8 inches or so wide and 6 inches deep, after the manner of those for Celery, and heavily manure the same, well breaking up the bottom and mixing it in, after which the Leeks should be planted a foot apart and be heavily watered, so as to thoroughly settle the soil about them and give them a start. For ordinary purposes very good Leeks may be grown in ground that has been trenched or otherwise well cultivated and enriched. If drills be drawn and large, deep holes made with a big dibber, into which the plants may be dropped or placed, so as to have only just the tops of the leaves standing out, and if a little soil is run in or water poured down into the holes, the roots will soon get a start and the plants grow quickly if kept free from weeds during summer. The hoeing requisite to accomplish this gradually fills up the big holes with earth, and by its means the stems of the Leeks become blanched and usable for the length of a foot or more without any trouble. Those in trenches, of course, require soiling, but that should only be done by degrees, and good soakings of liquid-manure given whenever they become dry at the roots.—D.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampt-on-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, rules, and notices every so often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

3723.—**Standard Azaleas.**—What treatment will these want to preserve them through the winter out-of-doors?—T. EDMUNDS.

3724.—**Moving a Christmas Rose.**—At what time of year can I safely move an old-established and large clump of Christmas Rose?—ISLANDIA.

3725.—**Ivy covered with black-fly.**—Is this fly injurious to Ivy growing on the outside of a house? If so, what is the best manner of removing it?—S. M. D.

3726.—**Caterpillars on Currant-bushes.**—Will someone kindly tell me what is the best remedy for destroying caterpillars on Currant-bushes?—O. E. C.

3727.—**Fertiliser in a garden.**—What fertiliser would be a good substitute for farmyard liquid-manure for pot-plants out-of-doors?—Bosses and Chrysanthemum?—M. D.

3728.—**Plants for a border.**—Will someone kindly name some good hardy border plants having scented foliage, and also any others with variegated foliage?—A. SAUNDRA.

3729.—**Pronunciation of Clematis.**—I should like to know which is the correct pronunciation—Clem-at-iss or Clem-a-tis? Do not botanists prefer the former form?—PAUSTIA.

3730.—**Weed-killer.**—Will somebody kindly inform me how to make a cheap and effective weed-killer for gravel paths, stating ingredients and probable cost of same?—SOUSSAIA.

3731.—**Hyacinths, &c.**—I have had splendid Hyacinths and Tulips out-of-doors. When foliage dies should I take them apart and keep dry till October, or leave in the ground?—ANSTY.

3732.—**Propagating Azaleas.**—I shall be glad if someone will tell me how I can increase the number of my Azaleas, Mrs. Van der Cruyssen and A. Mollis? I have a warm greenhouse.—H. B.

3733.—**Box edging.**—I have just planted some Box edging, which, owing to the different lengths of the plants, is very uneven. When shall I trim it level, now or at end of season?—T. EDMUNDS.

3734.—**Hollies.**—I moved some plants from 4 feet to 5 feet to height last February. They are now casting off all their leaves, and I fear I shall lose them. Can anything be done to give them a start?—S. M. D.

3735.—**Green-fly.**—I had the green-fly so much trouble amongst my flowers, I now can't bear get rid of it. Tobacco-smoke in the conservatory is so unpleasant, and spraying seems to do no good.—AMATEUR.

3736.—**Treatment of Vines from cuttings.**—I have struck several cuttings of a Vine, and I find they are growing. I shall be glad if someone will tell me the best way to treat them in a small way? I have a warm greenhouse, facing south.—H. E.

3737.—**Chip baskets, &c.**—I want chip baskets or boxes for Royal Fests to send tall Lillies in, measure, 2 feet 7 inches long, 10 inches wide, 7 inches deep, with lid. Where can I get them?—MRS. DYKZA, The Red House, Kenrick.

3738.—**Watercress for profit.**—Would anyone kindly inform me what profit might I expect from 1 acre of Watercress, doing all the work myself, and where can the Cress be disposed of? Would Covent-garden Market do?—BRINKHURK.

3739.—**Acacia armata and Oytisus in pots.**—I should be extremely pleased if anyone would kindly enlighten me with regard to the treatment of the above to bring them to perfection? My master makes a speciality of them.—NEW READER.

3740.—**Insects on standard Roses.**—I have some standard Roses which are attacked by small yellow insects, that perforate the leaves, and they then decay. Will someone kindly tell me what is the best remedy for this state of things?—TERRA.

3741.—**Clethra arborea.**—I should be glad to know how I am to treat a Clethra arborea, which I have lately obtained? It is growing in a 5-inch pot in greenhouse, and is about 18 inches high. Any information will be gratefully received.—O. E. C.

3742.—**Bulbs from South Africa.**—This is extremely obliged to "J. U. G." for his information as to how to treat the bulbs, and is she right in understanding that the Scytium should be plunged in a hot-bed now and kept there?—MRS. JOHNSON.

3743.—**Auriculas in the open air.**—Will someone kindly give me some information as to the best way of growing Auriculas in the open air? Should I sow seed or get plants? The soil in my garden is dry, light, and seedy, and I live over the sea.—RIS.

3744.—**Shrub seeds from New Zealand.**—Will someone kindly give me a few hints as to the raising and subsequent treatment of some shrub seeds which I have had sent from New Zealand? I possess a brated green house and a cold frame.—KENT.

3745.—**Greenhouse plants from seed.**—Will someone kindly advise me as to what seeds I should sow to supply a small span-roofed greenhouse with flowers during the autumn and winter months? Day temperature in winter about 55 degs.—S. M. P.

3746.—**Bone-meal for Chrysanthemum.**—Will "E. M." or some other experienced grower of Chrysanthemum kindly tell me if bone-meal as used by farmers for manuring purposes is good for mixing with soil for potting Chrysanthemum, &c.?—AMATEUR.

3747.—**Maiden-hair Ferns.**—I am anxious to grow these Ferns from spores. Will someone kindly give me full particulars as to how is the best way to proceed, where to get the spores, the best kind to have for conservatory and house decoration, time of year for sowing, &c.?—AMATEUR.

3748.—**Calceolaria californica.**—Would anyone be kind enough to tell me what Calceolaria californica is like, and whether it is good for bedding out? I have got a lot of them, and have never seen them before. They have brown stalks, and are very tender plants.—F. CLARK.

3749.—**Lily of the Valley and Carnations.**—Would someone kindly give me directions as to the management of Lily of the Valley in pots, so that I could have it so early as possible? Also what Carnations to grow for profit, and the best time to get them?—EDWARDS.

3750.—**Horchond beer.**—Will someone kindly give me a receipt for making Horchond beer, such as is sold to herb beer shops to Manchester and Prastoc? I have tried several times, but cannot get anything near it. Any information on the subject will be greatly valued by—THURST, Devon.

3751.—**Chrysanthemum for India.**—I should feel obliged to "E. M." for the names of three dozen Chrysanthemums, divided as follows: 1 dozen Japanese, 1 dozen Incurved, 6 Reflexed, 6 Pompons? These are intended for specimens, and to be grown on the natural systems.—LOWE BENOAL.

3752.—**Raspberry-canoe.**—Every year when my Raspberry-canoe are in blossom small brown flies come and settle in the flowers, leaving brown marks. When the fruit grows and is palled a small maggot is found inside. What is the cause, and what steps can be taken to prevent it?—E. P. COLMAN.

3753.—**Vinery.**—I have some ground on the borders of West Brighton, on which I wish to erect a house or two for Vines. Size of ground, 120 feet by 40 feet. Will anyone kindly advise best style of house, and if it should be heated? Ground runs east to west. Where should the Vines be planted?—WEST BRIGHTON.

3754.—**Using a fertiliser.**—I have been given some artificial Fertiliser, but do not know how to use it safely for pot-plants or for Roses out-of-doors? Should it be used dry on the surface, or should it be mixed with soil, or should it be mixed with water? I should be obliged for directions and proportions in any case.—ANNETT.

3755.—**Vegetables near Calcutta.**—Will someone kindly tell me the names of the best sorts of the following kinds of vegetables suitable for garden culture in a place near Calcutta? Best, 2 sorts; Cabbage, 2 sorts; Peas, 4 sorts (late kinds to be avoided); Tomato, 2 sorts; Cucumber, 1 sort; Celery, 2 sorts.—LOWER BENGAL.

3756.—**Rhubarb for show.**—I have some Rhubarb which I want for show. Will someone please give me a few hints as to its management? It has already got some very fine stalks, and I want to know what sort of manure will be best, whether liquid or otherwise, and whether I shall let all the stalks remain, or shall I pull out just a few of the oldest ones?—RUBBANS.

3757.—**Roses in a greenhouse.**—I should be very grateful for a little advice from "J. C. C." or some other experienced Rose-grower. I have a two-year-old Marechal Niel, planted out in a cool greenhouse. It flowered well early. I then cut it back, and have kept it pruned, with the result that it is now full of red buds 2 inches or 3 inches long. Should I thin out some of these, for in one place there are two or more on a joint? And should I discontinue liquid-manure? Also, when should I begin to give more air and harden off the young plants?—F. M.

3758.—**Plants for a Birmingham garden.**—Will anyone kindly tell me what vegetable or flowering plants would do well in a garden in the suburbs of Birmingham, in which Lillies of the Valley and Lettuce luxuriant? The garden is sunny and has very little shade, but hitherto I have been very unsuccessful in growing any kind of vegetables in it.—E. B. W.

3759.—**Weeds in garden-paths.**—My garden-paths are overrun with Couch Grass, &c., which is practically impossible to eradicate by the ordinary methods. I have decided to water the path with some powerful weed destroyer. Would someone with a similar experience kindly give me instructions for making a good weed destroyer, and also how same is used?—FERRELLAN.

3760.—**Treatment of Cucumbers.**—My Cucumbers-plant are growing too luxuriantly. What is best to be done? Lean to house, or fire, but a hot-bed. Soil, last year's manure mixed; matted soil, earth. Will it injure the plants if I cut away some of the shoots at the bottom? I tipped out the buds too soon, causing them to send out shoots too low down, thereby covering the beds.—SUBSCRIBER.

3761.—**A house conservatory.**—I have a conservatory built between my house and the sea, about 30 feet long by 6 feet wide, and 12 feet high. Glass roof and glass window at each end, on the first floor, with north and south aspect. Would anyone kindly advise me what to grow on the walls or on the stages? It is not heated, but frost can be kept out during the winter.—W. L. W.

3762.—**Tuberous Begonias.**—Will some experienced grower advise me respecting Tuberous Begonias? In February I bought some tubers, and put the large ones in pots and the others in boxes, which were then placed in a propagator, from which they were removed to the top shelf in an unheated greenhouse. Some of them are now 2 inches to 3 inches high. Should they be removed from the boxes into pots, and the others repotted, or leave them as they are for bedding out?—CONSTANT READER.

3763.—**Treatment of a Myrtle.**—I shall be glad if anyone will kindly tell me what treatment I ought to give my flowering Myrtle? It was a beautiful shrub, nearly 10 feet high, and bore splendid flowers. One severe winter it suffered by the frost, and has never recovered, the leaves bring now of a brown-green tint, the blossoms poor. I always cover the tree with a tent of straw now in winter, leaving a hole for air, but it does not seem to protect it, as it is now very bare, and the few leaves that are on top are quite brown.—H. P.

3764.—**Seedling Begonia-tubers.**—I should be very glad of some information about starting seedling Begonia-tubers? I got a dozen for bedding out from a nurseryman to first week of March, which were potted in tubs, and plunged in Cocoa-ouf-fibre in the propagator at a heat of 75 degs. for five weeks. Have since been standing on a sunny shelf in the greenhouse, but yet show no signs of starting. They have been kept just moist. Would some friend kindly say if the fault is in the tubers or to the treatment?—FIVE.

3765.—**Treatment of Vines and Pines.**—Thin wicker my Vines have had new soil, and have grown away very well with one shoot, but the hoppers are all withering just before coming into flower. I should be very much obliged if you could inform me the cause, as the gardeners cannot account for it? The Vines are in about 60 degs.; night heat the heat during the day is about 70 degs.; night heat from 65 degs. to 70 degs. Pines are just coming into fruit. What should the heat be, and should I give them any liquid-manure?—JAS. HOUSTON, JUN.

3766.—**Calceolarias from seed.**—I had a good collection of the above, which I raised from seed in the autumn. The plants were very healthy and robust, and during the last two months, with the exception of about half-a-dozen, they have all died. The lower leaves turned yellow, and gradually the whole plant withered away. I shall feel obliged if anyone can suggest the cause of my failure? The greenhouse that they were in was kept at a temperature of 45 degs. to 60 degs.—J. R.

3767.—**Carnations (Malmalson, &c.).**—Will "J. D. E." or any of your numerous readers inform me where I could obtain plants of the Striped Malmalson (Lady Middleton) and the crimson variety (Mrs. A. Waresque)? I have a quantity of R. Hole, Germania, Mrs. Mulr, &c., in pots in span-roof house (unheated). The flowers are about 23 inches in height. I want early flowers, but am afraid they will be weak. Would it benefit them to place them outdoors for a few weeks? I shall be glad of any advice on the subject.—S. H. S. R., Birmingham.

3768.—**Standard Rose not breaking.**—In October last I planted twenty-four Standard Roses (from a well known Exeter nursery), half of them are full of buds and in splendid condition, whilst eleven have not yet made any sign; some of them have still a few small eyes remaining to the same condition as they were six weeks before. The Roses are all in one bed, in leamy soil well manured, and have been well watered twice a week. The flowers are about 23 inches in height. I want early flowers, but am afraid they will be weak. Would it benefit them to place them outdoors for a few weeks? I shall be glad of any advice on the subject.—S. H. S. R., Birmingham.

3769.—**A Portugal Laurel, &c.**—In April last year I had a large Portugal Laurel re-plantated, plenty of water being given at the time and afterwards. It withered, however, during the summer, and last year, but it is not except a few. No new ones have appeared, but it is not entirely dead, as a few green leaves remain on it. If someone will kindly tell me what would be the best time to do so, I shall be much obliged? The same thing happened to a small Silver Fir, which is entirely denuded of all green, except the leading shoot. What can I do to improve these?—C. H.

3770.—**Roses Marechal Niel and Niphotos.**—I have a Marechal Niel, planted last autumn in a border in the centre of unheated span-roof house, and trained on a lattice. When planted it had two shoots about 6 feet long. The only pruning they received was to cut away about 2 inches of each. The wood in question, but all the leaves have fallen off for about 2 inches from the ends, and the lower part of the leading shoot. What can I do to improve these?—C. H.

position. It is making wood freely. Some of the blooms open all right, the majority do not. The stems turn black, and the blooms fall. Can you please tell me the disease and remedies? Ought I to prune the M. Nies? The plants have been syringed daily.—S. H. S. B., Birmingham.

3771.—Flowers for a sandy soil.—Will someone kindly advise me how to treat (for flower growing) the mean sandy soil of Sneyton (on Lantz hill)? When freshly turned up by a spade, it resembles sea-sand very closely, and appears to have an loamy matter or vegetable fibre whatever. Of course, I am aware that Roses are not to be thought of, unless I import clay, but what can I do for the average mealy perennial (shrub, climber)? I can buy (with some difficulties of delivery) estibum; leaf-mould I do not see how to obtain. Can any good be done with peat-moss-litter, which, at all events, is easy to obtain and to transport? Would it form a good vehicle for the use of guano?—A.

3772.—Trees, &c., for a garden-path.—I have a house with a long front garden facing due south, but well exposed to a westerly wind. Two long flights of steps lead up to the house, which is very elevated, and much above the level of the road. Before the first flight 11 steps I reached the victor has to walk up a long gravel path, 31 feet by 8 feet, bounded on the one side by my garden, and on the other by my next-door neighbour's path and garden. Now, I should like to make this gravel pathway more attractive, not only to visitors, but from the windows of my high house. Will anyone kindly suggest anything? I should like some trees that would arch over, and so in time form a nice arbour. Hoses and other climbing plants might do, but I should not enjoy the flowers much, as naughty boys would soon walk them away.—AMATEUR.

3773.—Garden frames.—I am very much obliged to "J. C. G." for his kind reply to the above query of mine. See GARDENING, April 22nd, page 97. I would be further obliged to "J. C. G." if he would let me know how I should fix the independent bellies, and if the pipes should be at the top or bottom (I mean at the north or south inside in the frames)? The pit runs east and west, and the frames face the south. Also, should the hot-water pipes be between the surface of bed and the glass, and if so won't it be too warm near the pipes for any plants? I was thinking that the pipes might run through the centre of the bed under the plants. Would this be right? Also state how I should make a flue? I might come to the conclusion of building one. Which would be best?—ENGLAND.

3774.—Rose questions.—Will some of your readers reply to my following questions about Roses: (a) The names of best dark Roses? I mean those kinds only whose flowers are substantial, full, and of good shape, and which are free-flowering. (b) Is there any difference between "American Beauty," H.P., and "Triumph de France," H.P.? I find them to be identical, except in names. (c) The names of two dozen best Roses for nois flowers, and no dozen most sweet-scented Roses? Those that are free-flowering should be selected. (d) I should be obliged if any of your readers who have cultivated the undermentioned Roses would inform me of the growth, time of flowering, quality and description of the flowers, and the blooming qualities of the undermentioned Roses: Gustave Pigeaux, H.P.; Gloire de L'Exposition de Bruxelles, H.P.; Janna Brownlow, H.P.; Raynolds Hope, H.P.; Salamander, H.P.; Sir Rowland Hill, H.P.; Emulsion, Bourbon Perpetual, L'Idéal, N.; Climbing Perle des Jardins, E.; Baphio, T.; The Queen, T.; Wahn, T. (c) The names of best orange-coloured Roses and best red Climbing Roses, either H.P., Tea, or Noisette?—LOWER HUNAL.

3775.—Tea Roses in a frame.—I have about a score of Tea Roses growing in a cold frame (span-roofed, 8 feet by 5 feet). They have broken strongly and are showing a good number of flower buds, but during the past fortnight some of the plants have suffered from mildew, owing, I think, to the difficulty in ventilating properly, whilst the sun has been so hot and the wind cold. I have now applied shading to the glass, and have syringed the plants with soft-soap and sulphur. The mildew has disappeared, but the Roses do not look so healthy as formerly. Half my plants are in pots, and half planted out in a bed of good chopped straw. Do they require any assistance in the way of liquid-manure or top-dressing? If so, how and when should I apply it? No manure was used at time of planting—last December. After watering and syringing some of the plants (notably Niphotes) lose a few of their leaves. How is this? The water is always used with the nozzle off, never cold. Would anyone kindly favour me with advice as to the points to be attended to in the successful culture of Tea Roses in a frame, and also give me a list of the most suitable varieties, the quantity to be desired being—1, Mildew resisting; 2, Perfect form and colour; 3, Freedom of flowering; 4, Free but not too vigorous growth? I would also be glad to thank "P. U.," "J. O. C.," and "A. H." for the help they have given me on this subject in the past.—F. P., North Cheshire.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3776.—Seedling Dahlias (Dahlia).—Keep up a heat of about 60 degrees, and give air during the day when the seedlings are above ground.

3777.—Cutting down Solanums (S. T.).—Prune them in closely, and plant out in good soil. Lift in autumn when in berry for the conservatory.

3778.—Cinerarias (K. G.).—The Cinerarias you send are a very good strain, the flowers of good form and substance, and the colours bright and varied.

3779.—Forced Strawberries (D.).—Ventilate the house, so as to prevent the atmosphere becoming stagnant, as that is, above all things, most conducive to mildew.

3780.—Lawn marker (L. M. A.).—There are now various machines for marking out lawn-tennis grounds, and we advise you to apply to some of the firms who sell lawn-tennis apparatus.

3781.—Lily of the Valley damping off (Micham).—The spike sent looks as if it were produced from an "eye" that had become too dry before planting. We cannot account for it at otherwise.

3782.—Coquilla Nuts (E. J.).—These are the fruits of Attalea foenicifera, a tall growing South American Palm. It also yields a quantity of fibre, used chiefly in this country for broom-making. It is called Pisceba.—J. J.

3783.—Lilium giganteum (J. R.).—The bulbs, before they attempt to flower, usually send out several bulblets. These should be separated early, and grown on in order to succeed the parent bulb in flowering.

3784.—Golden Feather (Edging).—This is best raised from seed annually. It is too late to sow now; it ought to have been sown in February in heat, and the seedlings would have been ready to plant out now.

3785.—Treatment of Rhododendrons (Surrey).—If the plants are lecky, you had better cut every branch hard back. The stems will then throw out fresh shoots during the present summer if looked after as regards water.

3786.—Lapageria rosea (C. R. S.).—It was quite right to put the plant in a small pot. As soon as the roots fill it you should shift the plant carefully into a larger one, allowing, say, an inch of new soil all round the ball.

3787.—Spiraea after flowering (R. S.).—Set them out in a good open border, and treat them liberally with occasional doses of liquid-manure through the summer. Next year they will be fine plants, ready for potting up again for winter flowering.

3788.—Cattleya intermedia (Orchid).—You should keep the plant growing strongly. There is every probability of the shoots flowering. It is a kind that starting in the manner you describe, frequently keeps flowering or a long time.—M. B.

3789.—Ground Elder in garden (L. B. T.).—This is a troublesome enemy to deal with. There is no remedy but complete eradication of every particle of root that you can get hold of. It will probably take you some seasons to clear the ground thoroughly.

3790.—Dianthus neglectus not blooming (M. B. R.).—We can assign no reason for the plant not flowering. It generally flowers when strongly healthy year during early summer. If the plant is thoroughly healthy we think you need only have patience.

3791.—Spiraea palmata not flowering (South-ron).—This is not a difficult plant to cultivate, provided the soil is suitable. It thrives best in a moist soil, in which there is a little peat, as its roots are fibrous. It ought to thrive to perfection in a sheltered spot.

3792.—Palm-leaves becoming brown (W. J.).—There is some error in treatment, and it is probable, from what you say, that the cause is excess of water. Palm-leaves do not want to be continually deluged with water, although when in active growth they require an abundance of moisture at the roots.

3793.—Tulips and Crocuses after flowering (E. O.).—Do not lift the bulbs until the foliage is quite decayed, and cutting the leaves will impair the strength of the bulbs. You may leave Tulips and Crocuses to the ground all the year round if the soil is light, and they will be the better for it.

3794.—Transplanting evergreens (Laurel).—It is late for transplanting evergreens, but if the weather should be at once showery and muddy, not useless, you may transplant them now. The chief thing to guard against in transplanting at this season is dryness of the soil and atmosphere. All the really hardy evergreens should succeed in Durham.

3795.—Piper excels.—H. B. sends one of this family for a name, and I cannot give it. If I called it Piper glabrum it might not be called in question for a long time, but some day the true name would be found out. I should advise you to send it to Kew, and kindly ask the director to name it. They used to have a great lot of species growing there.—J. J.

3796.—Oncidium Schlimi (Orchid).—This is a plant that does not require resting at any season. It is a very gay Orchid, and although found by Linden over fifty years ago, it has never become a well-known plant in our gardens. This Oncidium is said to be a very cool one, but I should advise you to keep it in the bright side of the Odontoglossum-house.—M. B.

3797.—Leaf of Mueharia amazonica turning brown (P. S. E.).—If the leaf is decayed it is of no use leaving it on the plant, and the bulb will not bleed if it is cut off even when green. It was a mistake to give the plant guano or any manure whatever. Stimulants are only required when a plant is in vigorous growth. Nothing induces disease more in this and other plants than over stimulation by concentrated manure.

3798.—Olanthes (Orchid).—You have done quite right with these Orchids, and have sown your reward. You should let the young growths remain where they are at the top of the old growths, and some time, say in about a month, you may shift these and your other bulbs into 6-inch or 7-inch pots. The old bulbs are useless, and they will rot away in the course of the season. Keep them growing, and do not give them too much shade.—M. B.

3799.—Oncidium Marshallianum.—C. Blount says he has a plant with a branched spike, and it does not appear to move in the least. He thought to have had it open before now. Well, I am afraid you do not exercise much patience, but are apt to look upon matters with an unwise eye. It is not yet time for this plant to be in flower. The end of May and the beginning of June is quite time enough for that. Learn to exercise a little patience.—M. B.

3800.—Cattleya Schroderi, &c. (Orchid).—This plant should be grown on strongly, and although you have had only one flower upon a spike, I saw a specimen yesterday in an amateur's collection which was bearing five flowers, and scenting the house with their delicious perfume. When it has finished its growth it makes up a sheaf, and, like Mendell and Triana, should be left to rot through the winter. I am glad to hear you are so much taken up with your Orchid culture, it is a delightful hobby.—M. B.

3801.—Coclogyne Massangana (Orchid).—I am glad you have invested in this plant, because it really is so very beautiful when in flower. Its peduncle spikes reach to eighteen inches or more in length, frequently bearing two dozen or more of its flowers, which are yellow and rich-bronze in colour. You must grow this Orchid in a strongly, giving it plenty of light and heat and a nice atmosphere. It grows freely under this treatment, and when strong enough it will bloom.—E. M.

3802.—Cattleya Gaskelliana (Orchid).—You are quite right in your supposition. This kind does flower upon the new growth soon after it has come up, and before it has become matured, so keep the plant, or plants, quickly growing until after the flowers are past; and after the growths are made up and finished off it requires to be kept comparatively cool and dry. This is the Cattleya that in my early days used to be known by the name of Labiata pallida. There are many varieties.—M. B.

3803.—Miltonia flavescens, &c. (Odontoglossum).—This is a plant of no horticultural merit, and if you have not purchased it, if you would be advised by me do not do so, for it is possibly not so beautiful, and such kinds should not be indulged in by amateurs. It is a very old species, having been introduced to our gardens over sixty years ago. It is also known by the name of M. stellata. The other two species, M. caudice and M. Clinevii, are fine species. You will find them commented upon in another place.—M. B.

3804.—Primrose and Polyanthus (J. W.).—Primroses are distinguished from Polyanthus in having no main stem developed; the flowers appear to spring from the same point as the leaves, whereas in Polyanthus, Oxlip, and Cowslip the flowers are always grown in umbelled fashion, terminating an erect stem. Polyanthus are generally coloured and often laced at the edges. The difference between the Oxlip and the Cowslip is mainly one of size, the former being twice as large as the latter. The botanical names are Primula vulgaris (Primrose), Primula elatior (Oxlip), Primula veris (Cowslip).

3805.—Epidendrum ciliare (J. Collins).—Yours is a very grand variety of this old plant, the flower being large, beautifully imbricated, and pure-white. You need not grumble about the plant, especially to me, for I did not sell it to you, our old I advise you to purchase it, so that I am in an sort of manner chargeable with your disappointment. I do not know why such a variety should be so much despised, for although not having broad sepals and petals to taste the eye, the Cattleya flowers, it is very pretty. There is one thing against it, however—it was introduced upwards of a hundred years ago, and consequently it is an old plant, and I think that is the secret.—M. B.

3806.—Repairing garden hose (Amateur).—The instructions you refer to are probably those given by "EXEN" to GARDENING, June 10th, 1883. They are as follows: Take 2 ounces or more of naphtha, into which drop as much shellac as it will absorb till of the consistency of thick gum. Cut some bandages of canvas, American cloth, or thin leather, spread the composition on one side of them, then had them tightly round the hose, and fasten firmly with a nail. Let it remain for a few days, then take off the waste. The hose must be dry before the plasters are applied. Keep the cement in a glass-topped bottle. It is good for many household jobs, and will not dissolve in anything except its own spirit.

3807.—Caterpillars on Gooseberries (Everett Burriss).—The caterpillars attacking your Gooseberry-bushes are the young caterpillars of the Magpie Moth (Abraxas grossulariata). Syringe the bushes with 7 lb. of soft-soap, the extract from 6 lb. of Quassia-chips, added to 100 gallons of water; then beat the ground under the bushes with the back of a spade to kill the caterpillars which have fallen to the ground. Or use 9 gallons of warm soda-half pound of soda, half a pound of salt, and a handful of soot. Or sprinkle the bushes with fresh soot, or lime and soot, early in the morning when the bushes are wet with dew. In the winter, carefully remove the fallen leaves and any rubbish from under the bushes, and any leaves which have not fallen, as the caterpillars hide among them during the winter, and the ground should be well dressed with lime.—G. B. B.

Names of Plants and Fruits.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—A. Pickard.—Polygala Dalmaniana.—Home Farm.—Impossible to name accurately from such dried-up specimens.—H. Stead.—1, Cytisus racemosus. 2, Yellow Bankswort Rose. 3, Ceanothus blue Variegated. 4, Fuchsia had all fallen off; send fresher specimens.—F. H.—Ribes aurum. A. M. G.—Cannot name; spoilt by being packed in dry cotton-wool.—Regular Reader.—We cannot name garden varieties of Petarognium. Seed to a grower.—Miss Briggs.—Bird Cherry (Prunus ladanu).—Cariole.—Hibroanthus elegans.

TO CORRESPONDENTS.

Doubtful.—There is no plant at "Blenheim Palace," or anywhere else, so far as we know, that is fed on raw beef. There are, of course, what are called insectivorous plants.—Rev. E. Wright.—The Peach-leaves are "busted," the effect of a cold substance sent to the roots. Lift the tree in the autumn, and blot off all affected leaves now, and encourage the trees to make the growth.—H. A. P.—Apply to Mr. T. S. Ware, Hale Farm Nursery, Tottenham, London.—M. F. K.—Gooseberry-caterpillar. Dress over with Hellebore-powder (a poison, remember). Directions for its use have often been given in GARDENING.—A Birmingham Newsagent.—Apply to Mr. T. A. Dickson, Florist, &c., Centre Avenue, Covent-garden-market, London, W.C.—Subscriber.—From the appearance of the leaf sent we should say that the plants in the greenhouse have been allowed to become infested with green-fly. Fumigate frequently with Tobacco, and syringe with clean water afterwards.—H. C. Sears.—Apply to Mr. A. G. Baker, The Lilies, 124, Beckett-road, Beckenham.

GARDEN AND PLANT PHOTOGRAPHS.

We beg to announce another photographic competition, when prizes to the amount of over Eighty Guineas will be awarded.

The subjects selected may be: Beautiful houses and country seats; garden landscapes; picturesque trees; plants, hardy and tender; Ferns; Roses; out flowers, prettily arranged; pretty cottage gardeos; our best fruits on the branch or branches, not in dishes; standard vegetables; good flower gardens, or any other objects of interest in a garden.

LIST OF PRIZES.

COUNTRY SEATS AND GARDENS.—A prize of TWENTY GUINEAS will be given for the best series of not less than six photographs of Tudor, Elizabethan, Jacobean, or other old English houses and their gardens, particularly showing the beauty of the house in relation to the garden. Picturesque old Farm and Manor houses will not be excluded from this competition.

GENERAL GARDEN AND PLANT PHOTOGRAPHS.—First prize for the best collection of general garden photographs, SEVEN GUINEAS. Second prize, FOUR GUINEAS. Third prize, THREE GUINEAS. This series may include subjects from any class, from either outdoor or indoor gardens.

FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering shrubs of all sorts.

BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, Cherries, &c., or such fruits, to be shown on the branches, not in dishes. No prize will be awarded to photographs of fruits or vegetables crowded in dishes.

BEST VEGETABLES.—A prize of THREE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get full representations of the best garden vegetables under the old genuine names. We do not want to exclude real novelties when they are such.

In any of the departments, if no collection of sufficient merit is sent in, no prize will be awarded. All competitors not winning a prize will for each photograph obtain receive the sum of half-a-guinea. In order to give all readers ample time to prepare good photographs the competition will be kept open until the last Saturday in June, 1893.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, also labels, especially those made of zinc (which should be removed when the photograph is being taken), and all like objects should be omitted from these photographs. The intention is to show the full beauty of the subject taken, and this cannot be done well when the photographer is confused by other considerations. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. In many of the photographs sent in for our last competition the subjects were much overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none sent the copyright of which is open to question. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 57, Southampton-street, Covent-garden, London, W.C., and marked "Photographic Competition." All competitors wishing their photographs returned, if successful, must enclose postage stamps of sufficient value for that purpose.

BIRDS.

3601.—Robins building.—The time of nesting varies a little, according to whether the spring comes early or late; but the regular season is from March to July, May and June being the months in which most nests may be found. They do not build in shrubs, but their favourite site is a hole on some wild bank sloping down from the side of a wood into a road or lane; they also build in holes or crevices in rocks, walls, outhouses, dust-hins, partly decayed branches or trunks of trees, in the ground at the foot of a tree or ivy-grown stump, in ivy on a wall, in a Been-stack, in pots of all kinds, whether banging on nails or lying on the ground; even in human skulls, or, in fact, any secure retreat of convenient size. The natural food of the Robin consists of worms, insects in all their stages, seeds, berries, and small fruits, such as Cherries and Currants. Boiled Potato, egg, and bread suit them.—A. G. BUTLER.

3600.—Feeding Canaries.—Give Canaries good clean Canary seed, fresh Groundsel, Chickweed, or a bit of Watercress two or three times a week, or daily if in the country. Very the diet with Millet seed, a pinch of Maw seed as a treat, or a few Hemp seeds. A little summer Rape seed makes a good change with the Millet and Canary, but I never mix Rape, Canary, and Millet together, as I find that birds prefer one seed to the others, and will savor all the food to get the one they like. When Canaries are nesting or have young ones they should be given herb-boiled egg, chopped very finely once a day in addition to their other food, and not so much green food. Canary seed bread, sold in penny packets and in sixpenny tins (Welham's), I find very good, and it saves the egg a little. In hot weather great care must be taken that no food turns sour in the cage, and that the egg is quite fresh, or all the young birds will be killed.—FLEUR DE LYS GULES.

—The staple seeds for Canaries should be the best Spanish Canary and German Rape. When moulting or breeding a little Hemp may be added as well as egg-food. Cattle-fish-bone must always be in the cage, and Watercress should be given from spring to autumn whenever procurable. Young Canaries should be fed on three parts of maize-wafers, pounded up with one third dry yolk of egg, damped and worked up with a pen-knife into a crumb-paste. Many made foods are advertised and largely sold for rearing Canaries upon; but some of these foods the birds show a decided distaste for, and none are so good or produce such strong birds as the mixture recommended above. This year I have already reared a nest of five (two of them twins produced from a single egg) upon this food.—A. O. BUTLER.

3492.—Treatment of a Thrush.—It is quite possible that the bird is a hen, in which case it cannot be expected to sing; the sexes are very much alike, and although some fanciers pretend to be able to distinguish them by their coloring and spotting, the differences described are not worth the paper they are printed on. The only reliable character which I have noticed is that (when trapped or netted) as the bird is taken in the hand a cock bird not only chatters, but utters a shrill trill or pea-whistle, whereas a hen either chatters alone or remains quite silent, snapping violently, however. You can try giving your bird a little kidney neat and ten drops of glycerine daily, for a week, in its drinking water, but I am afraid it is a hen.—A. G. BUTLER.

"Gardening Illustrated" Monthly Parts.—Price 3d.; post free, 6d.

"The Gardener" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 6d. Complete set of volumes of THIS GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, 30s. 12s.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 6d.; post free, 6d.

"Hardy Flowers"—Giving descriptions of up to 100 of the hardiest of the most ornamental species of plants suitable for their arrangement, culture, &c. Price and postage, 1s.; post free, 1s. 6d. London: 37, Southampton-street, Strand, W.C.

Catalogue received.—Catalogue of Plants, including Novelties for 1893. Messrs. James Veitch, Royal Exotic Nursery, 64, King's-road, Chelsea, London, S.E.

Drawings for "Gardening"—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

SPECIAL POMPONE DAHLIAS.

LOVELY GEMS for cutting, and exhibition fanes, and selfs, brilliant, exquisite, and free. Strong plants. 12 best varieties, distinctly named, 3s. 6d.; Pure-white Pompona Guiding Star, simply invaluable, 1s. 4s.; magnificent Cactus Dahlias, in superb variety, to name, 12 lovely kinds, 4s. strong free. (CARNATIONS): Mrs. Muir, grand white, 6d.; Gwendolen, yellow, 9d.; Reynolda Hole, apricot, 6d.; Ruby, salmon, 4d.; Gloire de Nancy, immense white Gloire, 4d.; true old Crimson Gloire, 4d.; Salisbury, 6d.; Mrs. Laird, rose, 6d.; Mrs. Laird, superb blue, 9d.; Mrs. BEDDER; Lobelia Emperor William, true from cutting, strong, 3s. 6d.; 4s. 10d.; Calceolaria Golden Gem, 1s. 6d. doz.; Dark Heliotrope, 1s. 6d. doz.; Harrison's Musk, 1s. 6d. doz.; Cactus Sunflower, perianth, 1s. 6d. doz.; Chrysantha, Mrs. Dezsgrape, 1s. 6d. doz., free.

ROSES, FLORIST, SANDY LANE, CHESTER.

SATISFACTION GUARANTEED.

TEN-WEEK STOCKS, German Antars, Phlox Drummondii, Zinnia elegans (double), Lobelia Emperor William, Lobelia Swanley White (true), from cuttings, Ageratum, Antirrhinum, Forget-me-not (blue), and Perilla, at 2s. 6d. per 100, post free. Also

GERANIUMS, Fuchsias, Celceolarias, Verbena, Petunia (double), Dahlia (single), Nicotiana glauca, Heliotrope, Cosmos, Ivy Geraniums, Centaurea candidissima (double white foliage). All strong plants at 1s. 6d. per doz. From—

J. CANN, VICTORIA NURSERY, PLAISTOW.

12 ORAND DISTINCT DOUBLE PETUNIAS, 3s. 3d. Perianth 1883 Single Geraniums, 7s. doz.; new double, 3s. 1893, 4s. and 3s. 6d. New Fuchsias, 1893, 3s. 3d. doz. Band for list of new novelties, free.—JOHN BORE, Burrow-hill, Chesterfield.

SUPERB PETUNIAS.—5,000 plants of my renowned, large-flowered strain, beautifully striped, blotched, and marbled, now ready, price 1s. 3d. per doz.; 2s. for 2s. 3d., in strong boxes and Moss. These are grand for window boxes, bedding, or town gardens. Tenth season.—RAYNEBROOK, field, Crawley, Sussex.

GERANIUMS, autumn cruck, scarlet Venus, 1s. 3d. dozen; 7s. 100; 60s. 1,000. Lady Sheelid and Ivy Leaf, 1s. 3d. dozen; 10s. 100; Calceolaria from open air, yellow or dark, 1s. dozen; 5s. 100. Carnations, Ruby Capita, 4s. dozen, post free.—A. ROSE, Crowborough, Sussex.

HARDY FERNS.—20 varieties, including Royal Fumy, recurva, montana, viridis, Ceterach, 50s. 5d.; 100, 4s. free. Osmunda regalis, 2s. 9d. per doz. free. Very large beautiful rookery Fern, well assorted, 6s. per 100, put on rail.—T. FOX, 5 New-road, Nawlley, Penzance

THE YELLOW FOXGLOVE.—Stately, handsome, and uncommon, but hardy and easily grown. 3 well-rooted plants, 1s. free, with cultural directions.—JOHN RAYNER, Avenue, Southampton.

GORGEOUS HYBRID MIMULUS, large blooms, brilliant colours, splashed, barred, and spotted in various shades, equal finest from the Carnations, with easier growth, in pots or open ground, a good plant, 1s. free, with directions.—RAYNER, as above.

A GEM FOR HANGING BASKETS.—Irrill, long Bellflower (Campanula fragilis), wreaths of lovely saucer-shaped blue flowers; hardy, easily grown 3 good plants, 1s. free with directions.—RAYNER, as above.

THE CLIMBING MAIDEN HAIR (Adiantum Clivense), runs 30 feet in season, exquisite, pale-green, feathery-divided foliage, clusters flesh-coloured, heart-like flowers; hardy, easily grown; 3 well-rooted plants, 1s. free, with directions.—RAYNER, as above.

DAHLIAS.—I each the following 6 beautiful large doubles: Mrs. Gladstone, Mrs. Langtry, Mont Blanc, Peacock, John Bennett, Duke of Edinburgh, P.O. in 6d., 12 var., 3s.; or 6 half-penny named show Cactus, including Juarez, 3s.; or 6 choice Pompones, 1s. 6d. All strong plants from single pots. Satisfaction guaranteed.—WILLIAM WELCH, Rush Green Nursery, Romford, Essex.

MY PRIZE DOUBLE STOCKS & ASTERS, double India Pink, Phlox Drummondii, Heli bryson, French Margolids, P. thurium (Golden Feather) 3d. doz.; 2s. 100. Mrs. Veitch's, or F. white, and Mrs. J.P. dox. Calceolaria Golden Gem and white Tobacco plants, extra strong, 1s. doz. 1s. 6d. worth free.—WILLIAM WELCH, Rush Green Nursery, Romford, Essex.

LOBELIA EMPEROR WILLIAM, 3s. 100; 50, 1s. 3d.; 75, 1s. free. This is extra strong bushy stuff, and true from cuttings.—WILLIAM WELCH, Rush Green Nursery, Romford, Essex.

20 SORTS Fancy Panies, including that gem of gems, Mrs. R. Niven, 5s.; 20 sorts Show Panies, including Mrs. Hunter, 5s.; all post free.—CRAMB, Dunblane.

20 BEST SORTS Exhibition Phloxes, early and late, 5s.; 20 sorts best Dahlias, a few of each class 5s.; 20 best sorts Violas, 3s. 6d., free.—CRAMB, Dunblane.

VIOLAS.—Best bedders are Brillack, white; Lottis, mauve; Royalty, yellow; True Blue, Skyark, white, edged blue; 1s. 3d. doz. free.—CRAMB, Dunblane.

PANIES! PANIES!—The following 14 fine exhibition vars. Lord Hamilton, Mrs. Mark, Tom Travis, Geo. Anderson, Mrs. Freeland, Kate Jamieson, Miss Jane Jamieson, Mrs. Storrer, or F. white, and Mrs. J.P. McConnell, J. J. Ashton, Lord Rosberry Alex. Old, M. A. Booth for 5s. JAR, C.A. RNS, Tunstall-road, Sneyd-land.

OLEARIAS, etc.—White, blue, purple, red, 3 var., 1s. 6d. doz.; 1s. 6d. 100. Roses, 1 var., 2s. 12 var., 3s. doz. strong, free. Camellias (Tel. 401), 30 seeds, 6d.; 100, 2s. 6d. strong, cheap. List.—BROUNT, Rotheland, Sussex.

CHRYSANTHEMUMS.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

FINAL POTTING.—No time should now be lost in transferring the most forward plants into their flowering-pots. It is a mistake to allow them to remain for so long in small pots that they become thoroughly root-bound, which cannot fail to give the plants a decided check in their after-progress. Directly the pots are full of roots a shift into larger ones is necessary, so that the roots may continue in a healthy state, and not as they are in small pots, so cramped and entwined around each other that it is difficult to get them to make a fresh start into new soil. The pots should be clean. New ones ought to be thoroughly soaked before using; if not the moisture is absorbed too hurriedly from the soil, which is an item to be avoided, as it entails more water to be given to the plants than is well for them, and it wastes the new compost too much before the roots have had time to catch hold of it. For the bulk of the varieties grown for the production of large blooms 9 inch pots are large enough. If a stock of larger pots are in hand, and they are wished to be made use of, I would advise that two plants be put into one pot, choosing, if possible, the same variety. This is preferable to employing pots too large, not only on the score of their being unworky, and take up so much space, but the plants do not thrive so well in them; facilities are not afforded for supplying them so freely with stimulants as when they are in smaller pots. It is during continued showery weather that large pots are detrimental to the plants. Where specimens trained plants are cultivated the pots should be larger, as so much more foliage has to be supported as to require more rooting space. Pots 10 inches and 11 inches in diameter are not too large for specimens of this class. Plants grown for decoration to give a quantity of bloom in preference to individual quality also require pots 10 inches in width at the top for the largest specimens; the smaller will succeed in 9-inch ones. Pompones and single-flowered varieties do not require larger than those 8 inches in diameter, except for these of extra large size. Some attention should be paid to preparing the compost for the final potting. Although the soil is but one detail of culture, the most elaborate mixture or the best of soil might be completely nullified by errors in watering and after-management. The chief component part is good fibrous loam, partly decayed, say out long enough to allow the Grass to decay. It is a mistake to stack it twelve months before using; the fibre has in most instances decayed ere that, and in this way the best part of the loam has departed. It is not possible to define the exact quantity of material for the compost to suit all localities, because the turf varies in its character in various districts in many degrees and stages from light to heavy. (Ed.) soils are also deficient in calcareous matter, which is absolutely necessary in

some form or other for the production of high-class blooms. Pounded oyster-shells supply to an extent this want in the soil; even then a handful of quicklime thrown in amongst the turf is most beneficial. Lime is also useful for the destruction of worms in the soil, as well as supplying a necessary ingredient. Loam that has been taken from poor land needs assistance. A good plan to enrich such soil is to soak it well in strong liquid-manure for using it. A similar manure, such as that from the cow-shed, is useful where the turf is light. Horse-manure, prepared as though for a Mushroom-bed, is a valuable addition in the case of heavy, retentive loam. Wood-ashes provide potash; this is a valuable assistant in producing blooms of high-class quality, as it assists materially the solidifying of the wood, and without which the finest incurred blooms cannot be grown.

CHARCOAL is valuable, as it not only acts as a store-house for ammonia, but it renders the whole body of soil porous, preventing stagnation about the roots. It is necessary that they be kept in a sweetened state. Thomson's or Innes' Vine-manure is a valuable fertilizer for Chrysanthemum; used at the rate of 2 lb. of the former and 3 lb. of the latter to every bushel of the compost, it materially induces a vigorous growth, without being unduly gross. To three parts of decayed turf add one part of horse-manure, one part of partly decayed leaves, wood-ashes, and charcoal at the rate of one-sixth part, and one the artificial manures named. In the case of heavy loam, I prefer to remove the fine soil from it by the aid of a fine sieve, retaining none but the rougher parts. The fine soil only tends to choke the free passage-way for water. To the inexperienced growers potting Chrysanthemums may appear of no greater importance than potting any ordinary soft-wooded plant; but high-class blooms cannot be had from plants with soft, sappy stems, which are the results often of improperly performing this part of their treatment. When they are potted loosely they grow strongly, and produce large leaves, but are devoid of that solidity which is essential to success. The soil should be rammed into the pot very firmly with a blunt stick. In soil of a light character it is hardly possible to pot too firmly, but it is not so necessary with heavier soil, as the water will not percolate so freely, and should the drainage become defective trouble may ensue. When the plants are potted firmly the growth is not so rapid early in the season, but it is rendered solid and firm as growth proceeds, and is more likely to mature in a wet autumn.

THE POTS should be well drained, placing one large crook over the hole at the bottom and packing others around it as hollow as possible. Over the drainage place a layer of freshly-cut turf, or the roughest parts of the compost, to prevent the fine soil washing down among the drainage. The soil about the roots ought to be quite moist before transferring the plants to the new pots. Do not cover the top of the ball of soil about the plant too deeply. Give a little to cover any surface roots that may have become bare through watering, but leave a depth of about 1½ inches to allow space for water, and top-dressing at a future opportunity. If the

soil is moist, as it should be, no water will be required for two or three days. After this time a good soaking may be given. The leaves of the plants should be syringed two or three times daily after potting to freshen the plants, consequent upon their not receiving water at the roots in the same way as previous to potting.

E. M.

3746.—**Bone-meal for Chrysanthemums.**—This is a valuable manure when mixed with the soil for potting the plants in and is also beneficial for top-dressing them later on in the year. There are two kinds—one that is simply ground to a powder, the other dissolved by the aid of sulphuric acid. For soil of a heavy character this last is the best, while the former is the more suitable for light soil. Mixed with the compost at the rate of 3 lb. to every bushel when transferring the plants to 5-inch pots, bone-meal is a valuable manure. It is a good plan to add the bone-meal to the loam fully a month before potting the plants; sufficient time is then given for the manure to thoroughly permeate the whole mass of soil; in this way its properties are more readily assimilated by the plants than when the meal is added at the time of using the soil.—E. M.

3751.—**Chrysanthemums for India.**—"Lower Bengal" will find the following varieties free flowering and of easy cultivation:—Japanese: Avalanche (white), Sunflower (rich yellow), Bonquet Fait (beautiful soft-rose), Edwin Molyneux (rich crimson seal gold), Lady Selborne (white), Maidee's Blush (bimsh-white), Mme. de Sevin (rosy-amaranth) Sonree d'Or (orange and gold), Val d'Andorre (red, shaded orange), roseum superbum (lilac-rose, tipped buff), Mrs. J. Wright (white), Peter the Great (lemon-yellow), Icourved: Mrs. G. Ruddle (white), George Glendy (lemon), Mrs. Dixon (orange-yellow), Lord Derby (dark-purple), Lord Woelsley (chestnut-bronze), Jardin des Plantes (bright golden-yellow), John Salter (cinnamon-red, orange centre), Empress of India (white), Lord Alcester (primrose-yellow), Prince of Wales (dark purple-violet), Barbara (bright golden-yellow), Jeane d'Arc (white, tipped lilac), Reflexed: Culliegfordi (scarlet-crimson), Mrs. Forsythe (lemon-white), Dr. Sharpe (Amaranth), Elsie (canary-yellow), Christine (pink), Chevalier Domage (bright gold), Pompones: Mme. Elise Dorden (soft-rose), Fanny (maroon-red), White Trevenna (white), Nelly Rainford (buff), Lizzie Holmes (broeze), President (deep rosy-carmine).—E. M.

3750.—**Weed killer.**—You are not likely to get any ingredients for manufacturing a weed-killer at home any cheaper than you can obtain the same article ready for use from those who advertise them in these pages; as a matter of fact, I doubt very much if you can do so cheap. You may, however, try sulphuric acid, and add thirty parts of water to it. If you have a large space that is weedy, why not use salt? If salt is laid on the weeds in dry weather it is as effectual as any of the weed-killers.—J. C. C. (Ed.) Get a good weed-killer such as advertised in Gardening Illustrated. Give repeated applications. There are many remedies advertised in the country, but none are so good as this.—C. T.

GARDEN WORK.

Conservatory.

The sun during the day is very hot; but the wind too often blows from the east, and in ventilating give most of the air on the southern sides of the house. Cold draughts mean mildew and insects on Roses and other plants. Pick dead blossoms and seed-pods from Azaleas, Heaths, and other plants as they go out of flower, and take the plants to another house, where there is a genial temperature, to encourage the new growth, and fill up with other plants coming into blossom. Hydrangeas will be a feature as well as numbers are grown. If water impregnated with iron is used, a blue tint will be given to the trusses of bloom; this often happens when the plants are potted in peat. Cuttings of the young shoots getting a bit firm will root at any time from this till August; a little bottom heat will hasten the rooting. I have generally rooted them in the bed that has been used for propagating bedding plants; they must be kept close and shaded till roots are formed. Hydrangea paniculata grandiflora, when well grown, comes in useful for the conservatory later on. Tuberosa Bogalans are now coming into bloom; when moved to the conservatory place in warm end of house at first, and keep rather close for a day or two. Keep Lilium Warreni free from green-fly by sponging, dipping or fumigating, whichever is the most convenient. Seedlings of Primula obconica, which were sown early, will now be ready for potting off. The young plants will do best in a cold frame for the summer, shifting them on into a cold pit or frame as soon as circumstances will permit. Very often the seeds of this Primula do not germinate freely. There is yet time to sow again in a warm house; and the old plants may be divided and started again in small pots, with free drainage and good soil. This is a very useful plant to a plenty of its had reputation in the soft soil to be produced by contact with it. Fuchsias now coming into bloom should be neatly staked, the cone or pyramid in the best shape, and usually on a neat stake in the centre of the plant is sufficient support. Where Fuchsias are grown for exhibition, the blossoms should be picked off to within six weeks of the day of show. Dautsias and other forced shrubs will now be sufficiently ripened for placing outside. The best treatment is to plunge the pots in a bed of coal-ashes; this will keep the roots cool, and the plants will not require so much water. Give liquid-manure to pump up the buds till the pots are full of roots. As soon as Spruce flowering, place them outside in a shady position for a time, and if a heavy rain comes plant out and keep moist. Very large plants may be cut into three or four and planted out in a moist spot. In a couple of years they may be potted up again. Put a few neat stakes to Double Petunias now throwing up the flower-stems.

Stove.

The earliest struck Polanthes, Euphorbias, and other soft-wooded, winter-flowering stuff will be ready to pot on. Keep them as near the glass as possible; they will be better in a low, rather warm, pit for the summer, keeping rather close at first, increasing the ventilation as growth proceeds to make the foliage robust, and hardy. Plants grown without ventilation must have stiff, firm leaves, and then fade before their right time; and plants with bare stems are not so valuable. The growth of clematis soon gets into a lunge if left without attention for a short time at this season, when all things under glass are as full of life and energy. Be very careful about the water used for syringing; unless it is perfectly pure do not syringe the foliage, but keep up the requisite moisture in the atmosphere by damping down, and by wetting the water in indispensable now during the hottest part of the day, or say from 10.30 to 5.30. This will still be necessary as the nights are very odd, but 65 degs. at night need not be exceeded from fire-heat.

Ferns.

Under glass Ferns must be shaded, or the fronds will lose that beautiful dark tint of green which is so much appreciated. Young specimens must not suffer for want of pot-room. It does not take long to form a specimen if one makes a start with robust, healthy plants. Some worst plants to grow to the top obtained by sifting up seeds of old specimens; in fact, these old specimens, when they get too large and unwieldy for any useful purpose, should be thrown away, and propagate either from spores or by dividing young, healthy plants only. In working up stock of any scarce kind of Fern, it is better to divide rather frequently, whilst the plants retain their full vigour. This is especially true of Adiantum Farleyense and others which do not produce spores. Spores of Adiantum, Pteris, and other hardy Ferns may be sown any time in pans or boxes. So fill not a matter of the very first importance, as Fern-spores seem to grow freely anywhere in a house devoted to them. They seem to grow freely in sifted ashes under the stage; and a patch of ooke-dust, placed there as an experiment, has a very healthy growth of young Ferns upon it. In another place a bit of heavy loam—ono might call it clay—was very productive of young plants; but there was always more difficulty in getting them established from the clay soil than from lighter substances. Ferns must have abundance of moisture in the atmosphere now, which may be supplied by damping stages, floors, &c. This is a good season for replanting Fern-baskets. I always use strong plants, especially the plant in the centre of the basket; but smaller plants can be used to fill in round the sides and bottom of the basket. But it forms a pleasant change to fill in the sides of the basket with the creeping growth of such plants as Penzance variegatum, Sedum carneum variegatum, Tradescantia vitifolia, &c.

Potting Chrysanthemums

This work must be pushed on now, so that the plants do not suffer for want of pot-room. The best number of Chrysanthemums grown in many gardens form a heavy lay upon the resources of the gardener. At no time should the plants be allowed to get dust-dry, or the leaves will turn yellow prematurely and fall off.

* In cold or northern districts the operations referred to under "Garden Work" may be done from the first of a fortnight later than here indicated, with equally good results.

Window Gardening.

Everybody is busy now filling window-boxes. I like to see the growth fall over and hide the boxes. To do this at first large, freely-growing plants will be necessary. I like where possible to fill the boxes, and let them stand in a cool-house for a time till the plants are well established. Very pretty are the boxes in which strong plants of Clematis Jackman are established in the ends, to be trained up the edges of the window as soon as the boxes are placed in position. I have had large boxes in which Clematis floribunda has been planted and trained along the front, the flowering-shrub being permitted to hang down loosely. Canary Peppers and other forms of Nasturtium will make a pretty display, either for training round the window or to hang over; but in windy situations these overhanging shoots are rather difficult to keep in condition. Use the sponge freely upon plants in boxes, especially Palms, Aspidistras, Azaleas, &c. Anything that requires a larger pot may have it now. Sow Primulas, Chierarias, and Calceolarias under squares of glass in a shady window.

Outdoor Garden.

Roses will require a good deal of attention now. Magrota in the curled up leaves must be hand-picked. Greenfly must be promptly met with liquid insecticide; soft soap, 2 oz. to the gallon, with 1 oz. of Tobacco-powder mixed with the soap and water. I find Tobacco-powder used in this way is just as efficient as when used dry, and it is very cheap. Unless any objection is raised to the presence of manure on the borders, it may be certainly be mulched. A covering of manure keeps the roots so comfortable. Anoniss are coming up very irregularly in consequence of the drought. I think it is useless to water unless the ground can be shaded. Watering may assist the seeds to start, but if the watering is neglected even for a day, the seeds just bursting into life will perish. A little water is a dangerous thing in a dry time; either water thoroughly or not at all. Bedding out has commenced in many gardens. Well bordered plants will bear a degree or two of frost without injury, but I would counsel those who are not over-looked not to take in a hurry. We may yet have a cold wave from Russia that will injure tender things. It is perfectly true the exceptional character of the season may run some time longer yet, and that the usual May frosts may this year be absent. Still, nothing will be lost by using a little caution in putting out tender plants. How beautiful the Tuted Panais are just now! Why doesn't everybody plant them more freely? There is nothing brighter or cheaper. For continuous blooming bury a layer of manure 8 inches deep in the ground. The roots will find it when the time of trial comes.

Fruit Garden.

Melons planted now will be ready end of July if well cared for. They must have bottom-heat to bring up the flavour. Plant in heavy loam, pressed firmly down to secure good growth that will bear sunshine, and be red-spider proof. Early morning ventilation will tend to keep off canker and other diseases. Early afternoon closing will push on growth with the aid of the bottled up sunshine. Strawberries, unless rain comes, must have water. Not a mere sprinkle with the hose, but by watering that will soak the soil around the roots. Liquid-manure from a farmyard tank, if available, is exceedingly valuable, and will save much expense in the purchase of artificials. Insects must be attacked with determination, and the best and cheapest means which is the outcome of experience brought to bear. For the Codlin-moth try the Par green. For the Gooseberry-apterpillar use Hellebore powder. In all those things judgment is necessary, and this, of course, includes promptitude in application. The propagator never kills his fern. Vines are making lateral growth freely. Never let sublaterals extend, but rub them out when small, especially below the bunches. Above the bunches leave one leaf. If there is any fear of mildew on Vines dress the pipes with liquid sulphur, and use a little more lime for a night or two. Vines cannot be dispensed with yet, but it is necessary to keep the fire-heat down during the day. The safest plan is to let the fire go out in the morning. Our usual plan is to make them up rather high at 11, and let the fire go out in the morning, the furnace to be cleaned out in the morning and the fire lighted not later than three in the afternoon.

Vegetable Garden.

Happy are the people who live in a district where the clouds drop latences in the shape of the frequent showers. Here, in the eastern districts, we have not had rain for many weeks. Not a single April shower has told the dust of March, and the vegetable grower who has not taken the precaution to dig deeply and manure liberally is in a bad fix. There are arrears of seed sowing to be fetched up in many gardens, but waiting for rain seems like waiting for the Millennium. However, crops which must be got on must have special preparations made. First, of all the land must be thoroughly moistened; not a mere sprinkle on the top, but enough water must be given to moist the moisture working up from below. Then, when the water has settled down, prepare the seed-bed, sow the seeds, and shade with something. I have used the net which have just been taken from sheltering the wall-trees, propping them up with forked sticks; branches of trees, or Ribwort-leaves laid on the surface will help the land to retain the moisture, and keep out the heat of the sun. Under such condition the seeds will germinate strongly, and afterwards, if rain does not come, the plants must be kept going by mulching, watering, and frequent surface stirring. Plant out Celery as required. This is an easy crop to shade and water. Mulch Peas, Beans, Cauliflowers, and lay little ridges of short manure between the Onions and Carrots. We are putting out Tomatoes against warm walls. The plants have been hardened in the open air, and the pots are so full of roots it was necessary either to report or plant out. Plants against a wall can be sheltered if necessary. Plant out Vegetable Marrows under hand-lights. A lichen-leaf can be laid over the tops of the light if we get cold nights, and in this exceptional season all things are possible. Wonderful has been the progress made by Cucumbers and Tomatoes under glass, but the work of stopping and tying has been almost incessant, and the watering has been heavy. Tomatoes growing in a dry soil will not set the fruit freely, especially with a hot sun shining fiercely on them.

THE COMING WEEK'S WORK.

Extracts from a garden diary from May 20th to May 27th.

Commenced planting beds and borders out with the usual kinds of bedding plants. I do not depend altogether upon flowers, as a variety of foliage plants are used, including Castor-oils, especially the bronze-leaved variety Gibson. Canas also are largely grown, but these large-leaved plants must have shelter. In windy districts the leaves always look ragged and torn with the force of the wind. Blue Gums and Acaia Iophantha, and the Striped Malze are also used, but the foliage plants will wait till the beginning of June. At present we are working out the hardest things, such as Calceolarias, Lobelia fulgens, Blue Lobellia, Sloaks, Astors, and Phlox Drummondii, and the well hardened "Geraniums" of the so-called section are all ready to be out now. Everything is flooded with water as soon as planted, and the surface assessed at the morning after planting, before the sun has had time to dissipate the moisture. Planted out Tomatoes near every bit of bare wall surface, not only on the south aspects, but east and west also. Everything with Tomatoes depends upon the season. If we get a reasonable amount of sunshine, the fruits will be ripened on the east and west walls, and so I have surplus plants, and there are here and there bare spaces between the wall trees which will be better covered. Put stakes to Delphiniums, Carnations, and other hardy plants that will need support by-and-by. If not now, and it is as well to have the stakes when the time comes for giving a tie, as this sometimes comes in a hurry. Tinned annuals, and as the ground is very dry, a good watering was given immediately after to settle the soil. A great deal of harm is sometimes done to the plants left by thinning if the holes are not closed in the same way. In the case of anything very choice, I generally scatter a handful of fine soil over the spot before the water is gone, and this leaves all firm again. Cut off Aralia Sieboldi and Grille robusta. These are both useful plants for furnishing. They are easily raised from seeds, and if helped on in a warm house, they soon become useful. Planted out the greater part of the Arum Lilies. A few of the strongest will be grown in pots for early blooming. Planted out Vegetable Marrows and Ridge Cucumbers under hand-lights. Remove laterals from Vines in all the houses. A look round is given every week, as no good comes of leaving laterals too long. Planted out more early Celery, and set out Lettuce-plants on the ridges between the rows. I have had splendid Lettuces on these ridges, the depth of soil evidently aiding them. Gave liquid-manure to Globe Artichokes; they want a good deal of feeding to produce large, succulent heads. Looked over Roses to pick off caterpillars. Afterwards gave a good wash with the syringe with a mixture of soap and water; liquid-manure had been given latterly two or three times a week. Thinned off some of the Peaches from trees on slope; I want fine fruit. Planted more French Beans and covered more Peas for succession. Planted New Zealand Spinach on a warm south border; this is one of the plants which revels in hot sunshine, either with or without water. Like all other things, it grows faster with plenty of moisture, but it will not perish when dry. Shifted Zonal Pelargoniums, and moved to cold pit; will be placed outside shortly.

3680.—Tap water.—I have never heard of water from the mains containing "a quantity of soda." As a rule, it is a good deal too hard, while soda would tend to soften it. If this is really the case a moderate quantity will be found beneficial rather than otherwise. Such water (from the works) is decidedly inferior to rain-water for all garden purposes, but the majority of growers near London and other large towns are obliged to use it to a great extent, and yet they obtain good results. If possible let it stand out in the sun in an open tank for a day or two before being used.—B. C. R.

—Although such water is not the best for any plants, it is not so injurious as you seem to suppose. Still, rain-water or that from a pond or open tank is the best. I think hard water does more injury to tender Ferns than any other plants. I have used such water as you speak of largely in my time, but have never seen any ill-effects. I would rather use water that contained soda than that which did not. Draw the water early in the day and expose it to the air for some hours before using it.—J. C. C.

3754.—Using a fertilizer.—You do not say what the fertilizer is, but most of the fertilizers may be used as a liquid-manure at the rate of half an ounce to an ounce to the gallon of water. They may also be mixed with the soil in potting at the rate of one to two pounds to the bushel of soil, or they may be scattered in small quantities—say a teaspoonful to a plant in a 6-inch pot—and watered in immediately.—E. H.

3757.—Fertilizer in a garden.—There are numbers of fertilizers, all more or less useful. I have always obtained the best results from a mixture of several than one alone. For instance, after subjecting plants to a course of one manure it has been found to be advantageous to change to a second. Soot is always handy and cheap. Nitrate of soda, sulphate of ammonia, Ichthomeo guano, &c., also all come in useful for a change.—E. H.

FERNS.

HARDY FERNERIES.

WHILE flowers are indispensable for the ornamentation of a villa residence, a collection of hardy Ferns forms an equally important addition, and when properly and tastefully arranged they may be made to assume as natural an appearance as they do in a wild state; the rustic appearance, too, of a hardy fernery forms an agreeable contrast to the more dressy portions of the grounds. It is difficult to lay down definite rules for the construction of a fernery, as much depending upon the position which it is to occupy and the space at command. In fixing on the site, the first thing to be aimed at should be a shaded, secluded nook—not one that can be seen from the windows of the mansion or cottage, nor yet from the flower garden, but a part that is unexpectedly come upon when walking through the grounds. The situation should also be one that is sheltered from boisterous winds. Moisture, too, is essential to the well-being of hardy Ferns, but this cannot always be given in sufficient quantity to carry them safely through hot summers. Anything like straight lines must be avoided. If the space to be occupied be long rather than broad, it should be broken up here and there so as to form miniature dells, recesses, and projections, but all should have as rustic an appearance as possible. The plants in all cases should be allowed sufficient space in which to develop themselves. Where outdoor Ferns have failed to do well, the ferneries have generally been cramped for room. What is wanted is breadth and length, height being of secondary importance. If the fernery be so arranged that it could be traversed by a narrow path from which the plants could be examined, all the better. The stones employed should be placed in as natural a manner as possible, and yet they should possess a certain amount of artistic arrangement. Anyone who has searched for Ferns in their native haunts cannot have failed to observe that they luxuriate in a light, sandy soil, and this must form, if possible, the main bulk of the fernery. I have, however, many times used Cocoa-unt-fibre mixed with turfy loam, and it has always appeared to answer admirably. For very delicate sorts a compost may be formed of peat, leaf-mould, and loam, with a sprinkling of silver sand to keep all open and porous, but the stronger sorts, as has been stated, will succeed best in loam without the addition of peat. When I use Cocoa-unt-fibre I find that it retains the moisture without becoming sodden. Fern roots, being generally of a wiry nature, will grow in almost any soil that is of ordinary texture, but it ought not to be heavy. Ferns dislike manure both in a solid and liquid form. In arranging the plants I would not separate the evergreen from the deciduous kinds, but so dispose of them that when the foliage of the latter dies down in the beginning of winter, there would still remain plants enough to interest the cultivator. I would, therefore, plant plenty of sorts that would retain their verdure throughout the winter, such, for instance, as the *Blechnums*, *Scolopendriums*, *Polystichums*, and *Polypodiums*. In planting, an error of too common occurrence must be avoided—viz., that of planting too deeply. Generally speaking, the crowns must be kept well above the soil, but they should be made firm, and the stronger-growing sorts should be planted first. Dwarf-growing varieties with fine fronds should have the most sheltered nooks assigned to them. If water exists in the fernery a place must be afforded for the Royal Fern (*Osmunda regalis*). A list of hardy Ferns would be out of place, inasmuch as cultivators have their own particular favour-

ites. I may, however, just add that a small fernery (as in the illustration) may be constructed in any shady corner where flowering plants will not succeed, and if arranged according to good taste and judgment, it will always be a source of enjoyment to the cultivator. T.

3731.—*Hyacinths, &c.*—If the bulbs are not in the way of anything else to be planted in the border, leave them where they are. I have some in the front of an herbaceous border that have flowered where they are continuously for the last nine years, and still show no signs of deterioration. If the bulbs are in risk of being injured by planting above them, take up the bulbs when the foliage turns yellow, drying them off in an airy shed, afterwards storing them in paper bags in a cool, dry room until the first week in November—planting-time.—S. P.

— It is not absolutely necessary to take up the bulbs, and they may be left undisturbed for several seasons without being removed if they show no signs of deterioration, but the best growers lift them every year when the leaves have quite died down, and stored away in a dry,

Ferns on an old wall.

cool place for the summer, if they have been previously well dried by the sun. You may also remove offsets, which should be kept in dry soil in boxes until the autumn. The great thing is to plant *Hyacinths* early in October, so that the bulbs are in the ground before frosts occur. Bulbs that have been forced need not be thrown away, as some do, but planted out in the autumn in the garden, where they give acceptable flowers in the following spring. The same remarks apply to the *Tulips*. I always lift mine at least once in every two years, and find that the results are in every way more satisfactory. I had a fine lot of the beautiful *carmine T. macrospolia*; the bulbs were not lifted for about three years and they did badly, but when lifted and put in a fresh soil and position they again returned to their former vigour, showing that lifting every two years—better if every year—is suitable treatment. Plant again before November, although *Tulips* suffer less from being out of the ground than some things, but the quicker they are in the ground after October the better. All bulbs should be planted then.—C. T.

— To the bulbs up when ripe, dry them, and keep in a cool, dry place till October.—E. H.

3723.—*Standard Azalea*—it is impossible to answer the question usefully without more information than the query affords. The deciduous *Azaleas* are hardly enough, and if planted in the right kind of soil there is no difficulty in preserving them through the winter. But I expect this question refers to the *Evergreen* or *Indian Azaleas*, and, if so, more information should be given of locality, &c., where grown. *Indian Azaleas* have been planted out in sheltered spots in many gardens, but I think they were more common forty years ago than they are now. The truth is, except in the warmest situation they do not thrive in the open air. I have generally found wherever the *Camellia* is a success outside there the *Azalea* may be planted.—E. H.

— If you mean the delicate greenhouse *Azaleas*, they would fare badly exposed to the trials of an English winter. There are so many classes of *Azaleas* that it is somewhat difficult to give a satisfactory answer. The hardy *Azaleas* are the *Ghent Azaleas*, varieties of *Azalea mollis*, and others of minor importance. A *India*, the greenhouse *Azalea*, will also live out in favourable spots, but it cannot be accounted hardy, nor would it be advisable to trust it in the open. But in some sheltered gardens in the south of England the white variety and others live out. They could be preserved by covering them with mats, &c.; but the better way would be to keep them in the conservatory or greenhouse, as the case may be. During the summer months they can be stood out, and, in fact, are better in the open. Stand them in a sheltered position, moderately shady, and on a hard bottom of coal-ashes, to prevent, as far as possible, worms from getting in the pots and choking up the drainage. Water well when necessary, and do not be led away by the moist aspect of the surface, which may simply arise through a few showers. Take in the plants again the autumn.—C. T.

3659.—*A cleanly plant stimulant*—A solution of either nitrate of soda or sulphate of ammonia, one ounce to the gallon, would be found very beneficial to most hardy herbaceous plants, and being perfectly clean, inodorous, and readily dissolved in water one or other would, I should say, answer the purpose as well as anything that could be named. The chief difference between the two is that while the nitrate chiefly promotes growth, the effect of the sulphate is more to stimulate and increase the induracence. Water the plants with a solution, of the strength indicated, of any of the foregoing once every two or three weeks, taking care that it does not touch the foliage. In wet weather the salts may be sprinkled thinly on the soil round the plants, when it will be washed down to the roots by the rain.—B. C. R.

— For pot plants you cannot do better than choose one of the special preparations advertised in GARDENING, always taking care to follow directions given with the material. An overdose is likely to be ruinous. Special manures require to be given with great care. But you enquire as regards herbaceous plants. The majority of these do not need any artificial manure, only a good, well-prepared soil, manured in the first instance, if such was necessary. Leave off muddling about with artificial preparations in regard to the hardy plants of the garden. In respect, however, to the *Begonias*, there is no harm in giving the plants a supply of weak liquid-manure, just as the buds are seen, as it helps the plants considerably. Do not give it too strong.—C. T.

— Nitrate of soda, I should say, would suit you very well, as when used with care it is a capital stimulant, and not disagreeable to use—at least, not more so than any of the other concentrated manures. As a liquid stimulant use half-an-ounce to one gallon of water, and for sprinkling on the ground a small tablespoonful in a circle 18 inches over. The greatest objection that I have to any of the artificial manures is that in the hands of inexperienced people they are likely to be used to excess, and then disappointment is sure to follow. They are so pleased with the effect of the first dose or two that they cannot resist applying more, and then they either kill their plants or they get plenty of leaves and no flowers.—J. C. C.

— There is nothing disagreeable about Iochtime sulphate. Nitrate of soda, again, is a very cleanly stimulant, as is also sulphate of ammonia. I have always found an advantage in changing the stimulants occasionally, or mixing two or three together.—E. H.

UNIVERSITY OF CHICAGO LIBRARY

INDOOR PLANTS.

SARRACENIAS.

I AM asked to say a few words about these plants by a reader signing himself "Richard?" This gentleman says he has bought a dozen, and thinks he has given too much for them, but with this I have nothing to do. You should have thought about the price before you paid for them, not afterwards. Well, these plants, if strong, should make nice handsome specimens this season. They are known as Side-saddle flowers, and are included amongst the insect-eating plants. Naturally, these plants grow in boggy, swampy land, and many people assert that they cannot be grown well out of a stove, but such is not the case, and last season only I saw plants growing in perfect vigour in a house in which no means of heating it had been provided, but all the sun that shone was permitted to fall upon them. To ensure success with Sarracenias, I have always found it best to use rather small pots, and to drain these thoroughly well, and I like to use a mixture of peat, Sphagnum, and well-rotted manure. If the plants can be placed upon the ground, they may be stood quite close together, and fully exposed to the sunshine, when an ample supply of moisture will rise up from the ground, if this is duly watered with a rosed watering-can night and morning, the drainage of the pots ensuring the carrying off the extra supply which the plants get, and which they appear to like, and the distance from the glass does not affect them injuriously. If this plan is not practicable—but they must be grown upon the stage—they should be plunged in Sphagnum Moss and similarly watered. I do not like the system of standing them in pans of water, although I must confess to have seen some very good examples grown in this way, but I do not think it is a system which will bear a continuance for several years, for these plants do not like anything sour or stale about their roots. In the autumn, when the pitchers begin to fade, less water must be given, but do not entirely withhold it at any time, and the plants may be stood close together for their winter's rest; and the best place for them is to select the corner of a frame or pit, from which all chance of frost getting at them is safe. Here they may remain until about the beginning of March, when they should be repotted and trimmed up for summer show. The young growth should be carefully supported or it is very apt to become injured, for when young it is very tender, and if the house is kept properly supplied with moisture, red-spider and thrips, their two greatest enemies, will be kept away. By attending to the above instructions, I think that "Richard" may be successful with his Side-saddle plants. J. J.

3660.—**Treatment of an Oleander.**—You should not touch the leaders of the Oleander, but let it grow on until it blooms, which will be early next spring, if not before. When in bloom three shoots will appear. The plant will then be about 3 feet high. Keep the leaves well washed. The soil I used was from an old Cucumber house, with a little fresh loam, which seems to suit mine well.—SOLDIER.

3789.—**Acacia armata and Cytisus in pots.**—Neither of these are difficult to grow. The plants will now have finished flowering, and, if any pruning is required, do what is necessary to put the plants into shape. In about three weeks repeat, if necessary, using good, sound, yellow loam and a little leaf-mould and sand, with free drainage. Keep them in the greenhouse till the growth is finished, or say till July, and then place outside on a coal-ash bed till October.—E. H.

3742.—**Bulbs from South Africa.**—No, the Satyrion should not be plunged in a hot-bed, but stood on an inverted pot in a cool frame. During the winter it requires a temperature of 45 degs. A cool corner of the greenhouse will suit it if it is not placed over hot-water pipes.—J. C. O.

3767.—**Carnations (Malmaison, &c.).**—You could get the varieties named at any good nursery, particularly the kind named Mme. A. Warocque, which I have seen several times lately in the largest nurseries around London.—C. T.

3741.—**Clethra arborea.**—You should keep the Clethra in the greenhouse and leave alone, if it is in good health and does not want repotting. It will succeed well in a greenhouse

and grow in time into quite a tree. If it requires repotting the best soil is one composed of peat or loam, mixed with a fair proportion of sharp silver sand. Give a fair amount of drainage, but if the plant does not need repotting leave it alone. The flowers are white, fragrant, and very pleasing. It was introduced in 1784 from Madeira.—C. T.

STAPELIAS AND THEIR CULTURE.

In reply to "J. H.," "M. Stanley," and others, Stapelias being natives of the Cape of Good Hope, they are greenhouse subjects. Though easily grown, many fail with them, saying they

Flowers of a Stapelia.

grew well for a time, and then decay. This I attribute to the climate they come from not being understood, and the common practice of taking it for granted that as they get a dry season it must be during our winter; so they are allowed to shrivel, the result of which is that when they should grow in spring the bottom often decays, and the plants get over it just in time to be served in the same way again. Now, every observer of Cape plants knows well that they have a tendency to grow freely during our winter, and though this growth may be retarded it must not be arrested; therefore, Ixias, Pelargoniums, and Heaths are exposed to all the light we can get, while the Stapelias are put on some out-of-the-way shelf. At the time we are getting our driest and coldest days the Stapelias at the Cape are getting their brightest and hottest; therefore, we ought to give them all the light possible, and as much heat as is compatible with it. Like other Cape plants, they don't like fire-heat, therefore they should be kept as far from the pipes as convenient; they stand the winter and flower better if exposed to the open air from June until September. It is best to strike fresh stock every season, taking the branches off at a joint to prevent danger of decay and escape of sap. April and May are the best seasons; put them in close to the edge of the pot, and keep them dry for a week, when water may be given, after which give it when quite dry. If they are well exposed to the sun they will strike in three weeks. Seed should be sown as soon as collected, or its vitality will soon be gone. Sow in shallow pans in light soil, and put them on gentle bottom-heat. As soon as well up put them on a shelf close to the glass, not potting off until well grown, as they often stand still for some time or die. Almost everyone who has written on these plants recommends sandy soil for them, but I find they grow best in a solid soil. Three parts loam and one broken brick is the best, excluding sand or manure. In this soil, with small pots, they grow freely, and though we have one species called *S. europaea*, or *italica*, yet I have seen it luxuriating above its natural growth in a temperature of 100 degs. Fahr. Seeds for transmission should be put into sealed bottles or oiled paper. The plants are very difficult to import. The best plan is by means of a small wooden box, using dry sand for packing material. C.

3745.—**Greenhouse plants from seed.**—Primulae and Cinerarias, including *Primula obconica*, may be sown now for autumn and winter blooming. In addition, try a few young bulbs of Cyclamen, and young plants of Zonal Pelargoniums may be grown on; and, of course, you must have *Chrysanthemum*. To have flowers in winter the night temperature should not be much under 50 degs.—E. H.

3762.—**Tuberous Begonias.**—I presume that "Constant Reader" intends all the plants for bedding out? If the leaves of those plants only in boxes do not intermingle they will not require other or separate plants, they will not require

disturbing until they are finally transferred to the beds. A cold frame would be the most suitable place for the plants now. The growth would be made more under conditions similar to that of outside, where the leaf-stalks are short, and less liable to damage from wind. When the plants are grown in heat, no matter how little, the leaves are rendered soft. The least exposure to sun destroys them.—S. P.

—As the season is now late I should either use them for bedding or pot them on, when they will make good plants for the greenhouse. In a few days now at the latest it is time to put out Tuberous Begonias, and keep them well watered for a time afterwards, if the weather is dry. They dislike very dry soils. If for the greenhouse pot them on and shade from the brilliant sun, as this has an injurious effect upon the leafage. Syringe freely, and give the plants plenty of air when the wind is not too keen. With ordinary attention they should succeed well and make a display.—C. T.

CHOICE BEGONIAS.

B. SCHARFFIANA.

This is a bold growing species, reaching a height of a yard or thereabouts, with stout erect stems and large bronzy-green leaves, veined with red. The most prominent feature, however, is the blossoms, borne in large densely packed clusters, and which from their weight assume a drooping character. The individual blossoms are of a pale-pink colour, while the sepals are at their base thickly clothed with reddish hairs, which become much less numerous towards the upper part. It is undoubtedly one of the very best Begonias, beautiful as many of them are, a great merit being that it will flower well on into the winter. Like the rest of its class, it is of easy culture, for cuttings strike readily enough, and as seed was plentifully offered last winter great numbers of young plants have been raised in this way. (See illustration on page 157.) P.

3764.—**Seedling Begonia tubers.**—All Tuberous Begonias intended for bedding should be started in a cool house; the growth is then stocky and not liable to receive injury from hot sun or cold winds when planted out. It is a mistake to subject the tubers to much heat; the growth is forced, resulting in soft, sappy stems and leaves, which are scorched by the first blink of sunshine which they encounter. If the tubers were alive when received, I should say it is owing to an excess of moisture that they have rotted. Nothing more than making the soil moist is needed in starting the tubers into growth.—S. P.

3773.—**Garden frames.**—Independent bellies of the Loughborough pattern are simply set in the wall by making a hole large enough to receive it, the face of the bellier being flush with the outside of the wall. The bellier may be put in at either end, whichever is most convenient for attending it; but in a general way they are fixed at the coldest end, which in your case would be facing east. With regard to the arrangement of the pipes, they should be between the bed of soil and the glass. You need not fear that the plants would suffer unless they actually touched the pipes. If you place the pipes under the bed of soil you would not get heat enough to keep out a severe frost. Seeing how much important matter there is wanting for space, I think it will be better for you to make up your mind first about making the frame. If you decide on doing so and will write again I will gladly help you. I may, however, say that although a flue would be the cheapest to begin with, a flue consumes more fuel than a boiler.—J. C. C.

3748.—**Calceolaria californica.**—I imagine you refer to the annual Calceolaria, which seeds and comes up freely in some gardens. The plant to which I refer has erect, stiff brown stems, which slightly branch, and the flowers are pale yellow in colour. It is, however, a poor thing compared to those commonly used for bedding. The present tender appearance of your plants evidently deceives you, as it is a hardy annual, and when required for bedding it should be raised in a cold frame in the spring. In many gardens it is quite a

ROSES.

3775.—**Tea Rosee in a frame.**—I think the plants are much too thick; a dozen in the size frame you mention should be enough. The weather has certainly been very trying for Roses in a frame, and it would have been much better if you had applied a little shading earlier in the season. I have no doubt the syringing solution was used a trifle too strong. Niphotos is a very sensitive variety, and often casts its flower-buds after a slight overdose of liquid-manure or an insecticide. Other kinds may be able to huddle through, but this grandest of white Roses is exceptionally tender. There are no Teas which resist mildew, but there are a few very much more subject to this disease than others. I name a few good Teas for your purpose; they having clear colours, medium growth, good size and form, with very free-flowering qualities: Anna Olivier, C. Mermet, Mme. Falcot, Souvenir d'Elise Vardon, Edith Gifford, The Bride, Sunset, S. A. Pison, Perle des Jardins, Mrs. James Wilson, Madame Hoste, Madame de Watteville, Madame Charles, Luciole, Ethel Brownlow, and Cleopatra. It should not be necessary to apply liquid-manure during the first season of your plants growing in such good soil—chopped turf—as you describe; but most likely the soil was rather dry, being fresh moved and stirred over previous to planting, and doubtless being raised somewhat as well. Then, again, if you use a strong solution freely, that also is apt to cause an unhealthy appearance, owing to the check such has upon the growing roots. Try and aim at a more medium treatment, both in watering, shading, and syringing.—P. U.

3757.—**Rosee in a greenhouse.**—You have started well with the Rose, and if you continue on the same lines you will get a splendid growth by the end of the summer. You may thin out the young shoots now—taking away the weak ones, of course—if there are too many. My own plants of *Mercéchal Niel* are in the same condition as yours, and I have left a sufficient number of young shoots to cover the available space at about 9 inches apart. Do not, by any means, discontinue the use of liquid-manure to the roots. This is just the time they want it most. With regard to giving more air, the young growth can hardly have too much in warm weather. It is, however, desirable to close the house at night for another month, and from October to Christmas ventilate the structure all you can both night and day, consistent with the treatment of any other plants growing in the house at the same time.—J. C. C.

From the wording of your query, I think you cannot have cut the plant back in the right manner. It should be cut back to the base of the plant. Your query reads as if you had only cut back each shoot that bore a flower to the base of these lateral growths. If not, and your plant is making many shoots from the bottom, I should be inclined to leave them a little longer so as to see which will come on the strongest, and then remove all but three. Keep the plants growing as freely as possible until the autumn; then admit air and ripen off steadily. A free supply of weak liquid-manure will be beneficial all through the summer.—P. U.

3740.—**Insecte on Standard Rosee.**—The Rose-trees are attacked with the Rose-maggot. The only remedy is hand-picking. If you examine the leaves that you find curled up, or any that do not appear likely to unfold, you will find the maggot inside of them. You must look minutely for the insects, so as to destroy them before they have time to eat their way into the flower-bud.—J. C. C.

From the description I think it is red-spiders that are troubling you. A thorough syringing is the only remedy. Use the solution about 70 degs. Fah., and have a little paraffin-oil with it; a wineglassful to 20 gallons of water will be powerful enough. It will be of no service unless you use the mixture freely, and also let it come into contact with the under part of the leaves.—P. U.

These are very destructive, and from the description I should think that they are the larvae of the Rose Moth (*Tipica ornithophagella*), which may be eradicated by hand-picking, the best remedy. Some growers

are much troubled with this pest. At the end of May or early in June the moths appear, the time depending upon the locality and the character of the season. The female deposits eggs, as a rule, on the buds, and the caterpillars hatch in about a month. When fully grown, they roll themselves into cases formed of bits of the leaves, and here in the soil a little below the surface. The larvae are yellow, with a black head, and ascend in the following spring, eating the leaves and tender shoots. The best of all remedies is to remove in the winter the soil about 3 inches in depth, eat, of course, disturbing the roots of the trees, and bury it at a considerable depth in another part of the garden, or burn it. The marauders are then killed. I should think that yours is the pest of what you have reason to complain.—G. T.

3768.—**Standard Rosee not breaking.**—It is difficult to judge of the reason your plants do not all break at once; but perhaps it is not a failure after all. You do not state if the plants are all Teas or not. If half Tea-scented or half Hybrid Perpetuals, it may be that the former have broken into young growth earlier than the latter, as they are inclined to do. Then we have had a particularly bad spring for newly-transplanted Roses. My own beds show somewhat the same evencness in breaking as yours do.—P. U.

3774.—**Rose questions.**—The following is a list of really good dark Roses that will give you every satisfaction. They are all full and of good shape and size. By dark Roses, I take it you do not mean the cherry-red varieties like Ulrich Brunner, Auguste Rigotard, &c., so I have left them out entirely. Abel Carrière, A. K. Williams, Charles Darwin, Charles Lefebvre, Countess of Oxford, Duke of Connaught, Duke of Edinburgh, Earl of Dufferin, Folair, Fisher Holmes, General Jacqueminot, Maurice Bernardie, Prince C. de Rohan, and Victor Hugo. These are the very best and you have a wide selection. Replying to your second query, *American Beauty* is not like *Triomphe de France*, but it is much like *Mme. F. Jansé*; *Comte de Paris* and *Baron Nathan de Rothschild* are also similar in several respects. Far too many Roses are introduced as new, when they are not really sufficiently distinct among such a vast variety as I now possess. You ask for a list of two dozen extra sweet-scented, also for one dozen extra sweet-scented. For cutting from I would strongly recommend the following: General Jacqueminot, La France, C. of Oxford, D. of Edinburgh, Fisher Holmes, Gabrielle

are no less than five varieties which are almost useless for you to grow; these are: Gustave Piganeau, Gloire de l'Expositioe de Bruxelles, James Brownlow, and Emotion. The remainder are good kinds, but a full description of each must be withheld; almost any nurseryman's list would contain them, and they would doubtless be pleased to seed you one upon application. You next ask for the best orange-coloured and best red climbing Roses. These are the best I know: Orange-coloured: Madame Falcot, Safrane, W. Allen Richardson, Rôve d'Or, Duchesse d'Auerstadt, Etiole de Lyoe, Jean Pernet, La Boule d'Or, Mme. Chauvry, Maréchal Niel, Perle des Jardins, Shirley Hibberd, and Sunset. Red climbers: Sir J. Paxton, Reine Marie Henriette, Chevalant Hybrid, Madame de Tartas, Climbiog Victor Verdier, Gloire de Margottin, Madame Isaac Periere, The Waltham Climbers, Nos. 1 and 2, and Fulgenc. If you desire any further reply, I shall be pleased to give you the best I can in another issue.—P. U.

3770.—**Rosee Marechal Niel and Niphotos.**—Your plants being newly planted, I should say you have either kept them too dry or else excessively wet at the roots. Either of these would have the effect you mention; so, too, would an overdose of liquid-manure. From your description the feeding roots of your plants have been suddenly checked in some way. If you were to syringe the plants freely during midday, and keep the house shut up too closely, with no shade, that would also cause the same effects as you describe.—P. U.

3735.—**Green-fly.**—No one need have any green-fly upon his plants if he would but adopt measures for their destruction before the enemy gets numerous, especially in small houses, where most of the stock is convenient to attend to. I do not believe that there is one of the remedies advertised for killing green-fly that is not efficacious when used in a proper manner, as there is no insect easier destroyed; but whatever remedy is used it must be applied in a proper manner. The easiest way of killing insects upon pot-plants is to dip them in a liquid solution of one of the many articles advertised. The best time to do this is late in the day when the house is closed, and creeps upon walls may be syringed at the same time. A large bottle of the prepared liquid, if kept corked, will keep good for several weeks, and when wanted for dipping it can be emptied into a bucket or other vessel.—J. C. C.

When plants are badly attacked by green-fly the effects will be visible for some time after the flies are destroyed. Liquid insecticides will kill green-fly if used strong enough, and if one application of any given strength does not settle them try again with the wash a little stronger. I have found Tobacco-powder and soft-soap very effectual. Two ounces of soap and one ounce of Tobacco-powder to the gallon of water used warm will kill green-fly, either by dipping, which is the most economical, or syringing.—E. H.

Dip the shoots of the plants in Tobacco-water, but a gentle fumigation is the best way to get rid of the pests, and if you are much infested with it I should advise this course. It is not pleasant, as you say, but it is a good remedy, and such things as *Pearl-onium* and *Rosea* are very difficult to get clear of green-fly, if some measure like this is not adopted. The dipping of the shoots or going over them with a brush dipped in a solution of Tobacco-water is a most tedious process. The smell of the Tobacco-smoke would soon pass away, but if you have decided not to have recourse to this measure apply such an insecticide as *Fir-tree oil*, or the other things advertised in this journal. Go by the directions given. An overdose is worse than none at all. Much good may be done by well syringing the plants, and after fumigation this should be done.—C. T.

3612.—**Lime water for worms.**—Clear lime-water will drive the worms out of flower-pots, but must be used more than once, for if it causes the worms already there to take their departure it will not prevent others taking their place in a day or two. In any case, I should be sorry to give it to very delicate plants. On the principle that "pre-

Begonia Scharifiana. (See page 156.)

Luzet, Mrs. John Laing, Anna Olivier, Marie van Hontto, Innocente Pirola, Safrano, Mme. Falcot, Mme. Lamhard, Niphotos, Perle des Jardins, Souvenir d'un Ami, The Queen, Souvenir de la Malmaison, Sunset, W. A. Richardson, Françoise Kriger, The Rogosaa, Homéro, and Isabella Spruet. Twelve good sweet-scented kinds are: C. Mermet, La France, Socrates, C. Riza du Parc, A. Colum, Annie Wood, General Jacqueminot, E. Y. Teas, Heinrich Schultzeis, Madame Cusie, Madame de Watts, and Souvenir d'un Ami. Your fourth query would lengthen this reply far too much, so I only point out that among the list given

vention is better than cure" I always use Porter's Inviscible Crookes for all plants in pots. I have no trouble with worms or any other vermin, as nothing can get into a pot where one of these is used. They last for a number of years, with the advantage of being very cheap. Several of my friends use them, and I have no doubt that they only require to be known to be generally adopted by all growers of plants in pots, being the very thing for that purpose.—E. W. H.

OUTDOOR PLANTS.

SOWING SEEDS IN DRY WEATHER.

The present season has, according to reliable statistics, beaten the record in the matter of continuous drought; but whether we get rain in time to save the crops or not, there is no doubt that we do not reckon upon drought as a very serious enemy to vegetation, for we look for April showers as regularly as the month comes round, and if the showers are absent the seeds fail to germinate; and the present exceptional drought will not be altogether to be deplored if it attracts more attention to the waste of water, and the very inadequate provision for its storage in gardens generally. Watering seeds is one of the things that need care, as stiff soils run together, and if allowed to get dry, are worse than if left entirely without; but, on the other hand, if artificial watering is done as regularly out-of-doors as it is done under glass, there is no reason why the results should not be equally satisfactory, and if you start watering at all out-of-doors make up your mind to continue it until the necessity for it has passed away. One of the lessons impressed on all this year is the superiority of drilling in seeds of all kinds over ordinary broadcast sowing, for with a fairly deep drill the seed is deposited at a uniform depth, and in ordinary seasons in moist soil; but if exceptional drought prevails water should be poured along the drills, and the seed sown right on the wetted portion, covering with dry soil. This will ensure rapid germination; but a good deal of the seed sown this year on the broadcast plan is still as dry as it was in the seed-bags, and will not germinate until rain falls, or artificial watering is done thoroughly. J. G., Hants.

A note on Tulips—If your splendid Tulips are required for a garden that does not admit of many varieties of one kind of plant, a choice selection would be the following: T. felgeae, T. Gesneriana, and T. macropetala. The first of the three is one of the finest of all the later blooming Tulips. The flowers are brilliant crimson in colour, quite self, and they are borne on tall stems. It is not difficult to grow, like the Turkestan Tulip, T. Greigi, and some of the other species, and is one of the cheaper, a few rare species being too expensive to purchase in quantity. A noble species is T. Gesneriana, the parent of the florists' kinds, particularly the form named major, sometimes called spatulata. A bed of this vigorous species, robust in leafage, and bearing bold, strikingly handsome scarlet flowers, makes a bright show. One sometimes sees very fine clumps of it in cottage gardens, making a bright, massy colour in the month of May. T. retroflexa is rather expensive, but it is a beautiful flower, pure yellow, with gracefully recurved segments. The three kinds named were especially selected recently from a large collection.—V. C.

3758. — Plants for a Birmingham garden.—You could grow Peas, Runner Beans, Vegetable Marrows, Beet, and such like vegetables with success, also Potatoes, if the soil is good, and possibly the fault has been in not having a sufficiently rich, well-worked ground. Vegetables require a substantial soil, otherwise it is hopeless to expect a satisfactory return. You give no particulars as to your treatment, character of soil, or locality, so it is somewhat difficult to advise you. As regards plants, you could grow many charming things if the soil is good, such as Tufted Pansies, so many delightful varieties, Auriculas, Roses, and Michaelmas Daisies for the autumn. Here are the names of a few things in addition to the above: Aletro-meria aurea, that likes a warm soil, and sunny position; the white Japanese Windflower, Anemone japonica alba, Aquilegia, Campanula

glomerata dehurica (rich blue), Corocopsis lanceolata, Delphiniums, Dictamnus Fraxinella, Doronicum, Eryngium amethystinum or E. plaeum (beautiful Sea Hollies), Fuchsia, Gypsophila paniculata, Hellanthus erygale, very charming in autumn, free, graceful, and bearing a profusion of yellow flowers on the slender shoots; Irisce, particularly the German kind; Lobelia

Verbascum phanicum. (See page 159.)

fulgeae, Evening Primrose, Lythrum salicaria roseum, a delightful rosy-flowered Loose-strife; Poppies, Rudbeckia species, Sedum spectabile, Tritomas, Crowe Imperiale, Carexons, Daffodils, Tulips, Hyacinths, and other spring-flowering bulbs. Of course, it is late to plant now, but you may get it at once Michaelmas Daisies, the Helianthuses, and autumn-flowering perennials, also many annual plants, as Poppies, Sweet Peas, Mignonette, and a few good bedders, as Tuberosa Bogoniae.—C. T.

3759. — Weeds in garden paths.—Such questioners are constantly being asked in GARDENING, and I am afraid many readers do not take full notice of the answers given. If the paths are overrun with Couch I should think they are in bad condition, and a thorough overhauling would be advisable later on. You may apply one of the many weed-destroyers advertised in GARDENING, and dull weather is best to choose for its application. Vitriol is a powerful remedy, but I do not care to advise the use of such preparations, which do more harm than good unless used with extreme caution. The liquid may be poured on to the paths with a fine-rosed pot, taking care to keep it away from the edge of the Grass. Several applications may be given, as it is necessary not to let the liquid soak into the edge of the path and kill the roots of the grass.—C. T.

3743. — Auriculas in the open.—As the ground for flowering is now over, it is scarcely worth while to get plants, as they may be easily

raised from seed. Get good seed and sow in July, and sow the seed in shallow pans or pots, watering the soil before sowing. You will, however, find full particulars about Auriculas in quite a recent number of GARDENING, May 6th, p. 134, where the question of seed sowing is fully gone into. From good seed you will doubtless get some fine flowers, and the way to secure a fine selection of Auriculas is to mark the plants when they bloom, choosing the very best colour, so as to obtain a good strain, as the florists call a selection of any flower. Clear, bright colour, the flowers well shaped, freely produced, and effective are what will best in the garden, not the shady shades that some affect to admire. Auriculas are more largely used each season for the garden, and they are delightful when in full bloom, the flowers very fragrant, and if the plants are robust a large quantity is produced on each tuft. But it is only by a process of careful selection that one gets this result. Of course I am writing of the purely border flowers, which are far more beautiful than the florists' kinds, the green-edged, and so forth, which must be grown in pots to get the characteristic and distinctive delineation of coloring.—C. T.

— I should advise "Rus," to buy a few named varieties of alpine Auriculas for this purpose. They are infinitely more satisfactory than unnamed sorts, if only a half-dozen varieties, and then cross at blooming time, and save his own seed for future sowing. He will be likely to get more enjoyment this way than any other. If a little decayed manure and leaf-mould were dug into the border in which they were planted, it would be all that the plants would require. I should like to ask your experienced grower and correspondent, "J. D. E., whether it is usual at this date (May 11th) for seed-pods of Auriculas to burst? In two cases, where plants have been crossed early—viz., Rev. F. D. Horner and Pizzaro, both have swelled seed-pods the size of good sized Peas. The outer cuticle has burst, I suppose, owing to the number of seeds developed, and they are to be seen lying exposed on the inner globular portion of the ovary. Will the seeds ripen in the usual way? And what can I do to prevent losing the seed? —FRED. T. POULSON.

3658. — Dandelions on a tennis-lawn.—A sure way of exterminating these is to keep cutting them off throughout the growing season. With a sharp long-bladed knife cut as deeply into the ground as possible, so that a good portion of the root is cut out. Continue to do this every time the leaves appear, and they will get weaker, and will eventually die out. Nothing can resist this for more than a season or two, as the roots do not get nourished, and rot away in the winter.—J. G. B.

— The best way is to go over the lawn carefully and spread out the offending plants, being cautious not to disturb the turf more than necessary, or to leave holes. An old knife is a good implement for the purpose, and answers as well as any more elaborate appliances. Bare spots may be made good by filling up with fresh pieces of turf, and give the whole a good rolling. Avoid any preparation such as vitriol on a lawn, otherwise the Grass is sure to get much injured. You could go over a good-sized lawn in a comparatively short time with an old knife to cut out the Dandelions. The quicker it is done the better.—C. T.

3771. — Flowers for a sandy soil.—I am afraid you are taking a depending view of the case, as from what I know of soils of similar capacity to yours, there are many flowers that you can choose with every prospect of success. Even Roses on the Manetti stock will do fairly well if you manure the ground well at first, and make the bed about 4 inches below the surrounding surface, and every spring fork in a dressing of English Guano. In every case keep the surface of all flower-beds and borders below the level of walks and surrounding ground, and always keep on hand a store of Peat-Moss-litter, which, when broken up, is a capital material for laying on the surface as a mulch to prevent the evaporation of moisture from the soil. Looking at the cost of transport the guano referred to is the best substitute for manure you can get, and may be safely used for any kind of plants or trees. The principal plants to avoid are those with thick, fleshy leaves. All the Dianthus family, which includes Carnations,

Pinks, Sweet Williams, and the Mule Pinks, would quite happy with you. So would the Rocky Mountain Columbines, if you water them in dry weather; also the single forms of Pyrethrums. With a thick mulch and a position shaded one half of the day, the Tufted Pansies will thrive. The Scotch Rosee and also the Austrian Briers would no doubt do well, and I would certainly venture to plant a bed of the Tea-scented varieties. Such hardy perennials as Iberis coronata, Alyssum saxatile compactum, and several of the low-growing Campanulas may be sown with safety.—J. C. C.

3724.—**Moving a Christmas Rose.**—If it can be moved entire with a large ball of earth the removal may take place in the end of the summer or beginning of autumn. If it is intended to divide it up to make stock, the spring, just as the new leaves are breaking away, is the best time; but old clumps broken up take a long time to get established, and I am always reluctant to break up or remove old clumps of the Christmas Rose.—E. H.

— The best season of the year to divide the Hellebore is in the late spring, and some do the work in the summer; but a large grower of the Christmas Rosee for the trade always divides in spring, and during the summer keeps them well supplied with water; also mulch them with either well rotten manure or Cocoa-nut-fibre refuse, the former for preference. If you have no special reason for lifting the plant I should not do so, as the Hellebore does not like disturbance at the root. The plants will succeed in ordinary soil, but like a moist shady place. Some of the finest specimens I have seen were those established by the side of a shady ditch in moist, peaty soil. Three of the finest varieties are St. Brigid, Bath, and maximus, each bearing well-shaped flowers, pure white.—C. T.

— Directly after the last flowers are cut is the best time to move any of the Hellebore family. The new growth is just on the move; the plants are at once into free growth, and do not feel the check, providing, of course, sufficient water is given the roots to prevent the leaves flagging.—S. P.

3673.—**Lily of the Valley in a bed.**—When Lily of the Valley grows into a crowded mass the flowers must be wanting in quality. Take them up carefully early in November, and make a fresh bed. Dig the ground deeply, working in a liberal dressing of rotten manure, for this plant loves an abundance of rich food. Select the largest crowns, and set them out 4 inches apart; the smaller ones can be put by themselves, and with a season's good growth will come to blooming size. Give them a top-dressing of rotten manure annually, and you will get an abundance of good bloom.—J. C. B.

3672.—**Auriculas.**—The side shoots, if taken off without roots, will form them if inserted as cuttings round the sides of small pots of sandy soil, with free drainage, and placed under a hand-glass or in a close frame; but the simplest and best plan is to obtain a few roots with each offset, as then they do better and with less trouble. Keep them in pots throughout, plunging them if possible in sahes in a cold frame for the winter. If several are inserted in a pot in the first place, they should be potted off singly as soon as well rooted. The plants will bloom nicely in 3 inch or 3½ inch pots, and indeed they do better, at any rate while young or small, in small sizes than larger ones. Keep them in a shady place during the summer, and the soil always moderately moist.—B. C. R.

— The best time to deal with the common border varieties is the early autumn, as then the soil gets well settled before the winter, and they have not a hot summer to go through. I should deal with them, and prepare a good, well-prepared piece of ground for them, where they should succeed well. It is most important to do this work early in the autumn, so as to get the plants established before winter frosts set in. You could take off the offshoots without roots, but it is better to get well-rooted crowns; there is less trouble, and they are far more likely to succeed well. This applies more especially to the florists' varieties, not the common border kinds, which are far more easy to deal with. In regard to the florists' kinds, the end of March is a good time to remove offsets, putting them in small pots, and using a light soil. If, say, a vigorous offset is taken in March, it will soon make a good flowering plant. Offsets taken without roots often remain a considerable time

before they start into vigorous growth, and send out strong roots. Put unrooted offsets into a hand-light, and keep close; only remove the top to let in air, and dry up superfluous moisture, otherwise they will damp off. If you have good border flowers, always take care to select the best colours and increase your stock. It is in this way that I can get a good selection, weeding out the poor, watery tints, which are ineffective in the garden. Also raise seedlings to get new colours, and the best time for this work is as soon as it is ripe, which will be in July. There is time to save seed.—C. T.

MULLEINS.

The Mulleins in cultivation in gardens are for the most part of only biennial duration. They are somewhat unsatisfactory plants to deal with on account of this, and also on account of their extreme susceptibility to cross-fertilisation. It is almost, if not quite, impossible to keep them true to name when a collection is grown;
